OF THE

CHURCH OF SARUM,

THIS

#### INTRODUCTION TO GARDENING,

IN ACKOWLEDGEMENT

OF MANY AND GREAT FAVOURS, IS,

WITH THE SINCEREST RESPECT AND GRATITUDE,

INSCRIBED,

BY HIS MUCH OBLIGED

AND FAITHFUL SERVANT,

THE AUTHOR.

## PREFACE.

considering the several well-received Books extant on the subject of Gardening, the Author of this seels himself stattered, that it has so soon come to a Third Edition; and he has (with zeal) embraced the opportunity of making every Improvement in his power, to render it still more acceptable to the Public, and trusts to have served the Cause of Gardening in a way that demonstrates his attention and industry in so savorite a pursuit. He has concentrated information with no little pains (particularly in the Lists and Calendar) and hopes that the Work may be found useful to all who consult it. For the Young Gardener, however, it is chiefly designed, and meant to be his easy Introduction to the Art,—his plain and sure Guide.

"Hints on the Method of managing POND-FISH," inferted at the close of the Book, are written "by a Member of the Imperial free Agricultural Society at St. Petersburg,"—a very respectable Literary Character, to whom Mr. M. is much obliged by the communication. The breeding, feeding, and preserving Fish is a part of Rural Economics too little attended to, so that this Paper will serve at once to recommend, and instruct on the subject, those who may be disposed to make experiment in it.

## CONTENTS.

#### SECTION I.

#### PRAISE OF GARDENING.

it, by Lord Bacon, Mr. Cowley, 2. Anonymous, Mr. Evelyn, Mr. Addison, 4. Mr. Harvey, 5. Mr. Cowper, Sir William Temple, 6. Le Pluche, Virgil and Mr. Cowley, 7.

#### SECTION II.

#### CONCERNING VEGETATION.

Of earth, 8. Of water, 9. Of air, 10. Of fire, 11. Of light, 12. Of nature; of feeds, 14. Of plants, 17. Of roots; of stems; of leaves, 18. Of branches: of buds, 20. Of flowers, 21. Flora's festival, 23. Of atheism, 24.

#### SECTION III.

#### OF THE FORMATION OF A GARDEN.

In general, 25. Of fize; of fituation, 26. Of screens; of form, 27. Of the soil; of best fruit wall, 28. Of its border; of intersecting walls, 29. Of wall trees; of distances, 30. Of intermediate spaces; of plums, cherries, and pears as wall-fruit, 31. Of apples and mulberries as ditto. Of evergreen hedges; of gravel walks, 32. Of edgings, 34. Of grass walks and others; of standard trees, 35. Of dwarf standards and espalier trees, 36. Of distances; of standard apricots, 37. Of currants, gooseberries, raspberries, and strawberries, 38. Of shrubs, asparagus, artichokes, and herb-beds, 40. Of slowers, and water, 41. Of mixed gardening; of a flower garden and parterres, 41, 42. Of an orchard, 43.

#### SECTION IV.

#### OF THE CULTIVATION OF A GARDEN.

What it is, 45. Of trenching and manuring, 46. Of cropping, 47. Of weeding, earthing up, digging, and of thinning crops, 49. Of pricking and planting out; of over cropping, of dibble planting, and of watering, 50. Of shading; of plants requiring water, and of watering wall-trees, 51. Of the quality of water, 52. Of management in general, 53; and particulars, 54, &c.

#### SECTION V.

#### OF PROPAGATION.

Of good feed, 57. Of new and old feed, 58. Of faving feed, 59. Of preparing feeds, and feafon for fowing, 60, &c. Of fuccession crops, and of sowing on fresh ground, 61. Of the depth to sow at, and quantity to be sown, 62. Of covering feeds, of patches, of thinning, and of propagation by suckers, 64. By slips, offsets, and division, 65. By suttings and layers, 66, &c.

#### SECTION VI.

#### OP A NURSERY.

Its uses, 69, &c. Of the soil, &c. 70. Of fruit-stocks, 70, 72, 73. Of tree seeds and sowing, 71. Of management, 72. Of protection, and of planting out seedlings, 73. Of raising apple trees, 73. Of pear, plum, cherry, fig, and quince, 74. Of mulberry, medlar, grape, and chesnut, 75. Of walnut, silberd, currant, gooseberry and berberry, 76. Of raspberry and strawberry, 77. Of raising sorest-trees, and of good seed, 78. Of management, 79, 72.

#### SECTION VII.

#### OF GRAFFING.

Nature of, 79. Of skill in performing, 80. Tools for the work, and of heading stocks, 81. Of scions, 82. Of cutting outting cions, time of graffing, and of cleft-graffing, 83. Of whip-graffing, and of flicing, 85. Of bark-graffing, 86. Of fide-graffing, 87. Of approach-graffing, or inarching, 88. Of budding, or inoculation, 89, &c. Fruits usually budded, and of proper flocks, 90. Method of budding, 91, &c. Of buds that have taken, 93. Of beheading the flock, and observations on the whole, 94.

#### SECTION VIII.

#### OF PLANTING.

Choice of plants, 96. Act of planting, 97, &c. Of protecting roots, 98. Of watering and staking, 100. Of late planting; and of the soil in general, 101, &c. Of the soil which suits each fort of fruit, 103. Of situation, 104, &c. Of season for planting, 106. Advice on the whole, 106.

#### SECTION IX.

#### OF SHRUBS, SHRUBBERIES, &C.

Value of shrubs; of raising them; times for planting deciduous and evergreen sorts, 117, &c. Of preparing the ground, 108. Of the act of planting shrubs; their disposition, distance, and situation, 109, &c. Of slowers for shrubbery borders, 110. Management of shrubberies; of hedges, or divisions, 111. Of covering old walls, 112.

#### SECTION X.

#### OF FOREST TREES.

Planting them recommended, 112, &c. Of the method of doing it, and preparing the ground, 114. Of underwood; of distances for timber trees, 115. Of plantations, single trees, and avenues, 116. Of season for planting; size of trees; act of planting and fencing, 117. Of dressing and thinning; of ornamental trees, 118.

SECTION

#### SECTION XI.

#### OF RURAL GARDENING.

Recommended, 119. Advice about; works of art, 120, 127. Hints to be attended to, 121, &c. Inclosure for exotics; of walks, 122. Of flowery decorations; of the introduction of water; of anticipation, 123. Shenstone on rural elegance, 124. Ornamental gardening; means of affecting it, 126, &c.

#### SECTION XII.

#### OF PRUNING.

Wall trees require skill, the obtaining which recommended, 129. Of their proper form; of heading young ones down, 130. Method of training, 134, &c. Of regulating trees in fummer, and of nails and shreds, 133. Of the hammer and of trellises, 134. Constant attention necessary; of their health, 135. Causes of injury, and means of benefit pointed out, 136, &c. Of their fruitfulness, how to provide for, 139. Of thinning the branches, 140. Mode of bearing; of shortening shoots, 141. Of furnishing wood, 142. Time for winter pruning, 143. Apricot, particulars of, 143. Re-pruning and frequent training, 144. To preserve blossoms, 145. Of thinning the fruit, 146. Of gathering it and its dropping, 147. Of pruning vines, 147, &c. Of figs, 151. Of pears, 153, &c. Of apples, 156. Of mulberries, and of cherries, 157. Of plums; of filberds, 158. Of currants and gooseberries, 159.—Thus far as to wall-fruit. Of pruning espalier trees, and of heading young ones down, 160. Of standard forts, 161. Of moss on trees, 162. Of pruning shrubs; raspberries, 164. Berberry; strawberry, 165. General directions for pruning flowering shrubs, 166. Particulars for the rose, honeysuckle, sweet-briar, and lilac, 168. Laburnum, jasmine, senna, syringas, hypericum frutex, spirea frutex, gueldre rose, and pyracantha, 168.-Forest trees for pruning, see section X.

SECTION

#### SECTION XIII.

#### OF HOT-BEDS.

Their use and nature, 169. Errors to be avoided; place proper for them; working the dung, 170. Dung-hills, care of; fize of beds, 171. Of moulding it; substitutes for horse dung, 172. Method of making a bed; quality of the dung; of unsoiled straw-beds; of grass-beds, &c. 173. Of bark-beds: to increase the heat of a bed, 174; to decrease the heat; uses for which hot-beds may be made, 175.

#### SECTION XIV.

#### OF RAISING CUCUMBERS AND MELON'S.

Early crop of cucumbers, and time to begin, 176. the bed and of moulding it, 177. Of fowing, and to be repeated, 178. Of pricking-out, and particulars of management, 179, &c. Of burning, 181, 183, 185, 186. Of watering, 180. Of a fecond bed, and of fleaming, 181. Of covering, 1821 Of stopping the plants; of the fruitbed; of earthing it, 183. Of planting, 184. Of shifting potted plants, 184. Of management in general, 185, &c. Setting the fruit, 187. Of pruning, and of fecond crop, 188. Of third crop, 190. Of faving feed, 191. Of melons; time to fow, &c. and of the feed, 192. fowing, airing, &c. 193. Of fecond bed; of third bed for fruiting; and of foil proper, 194. Of planting, pruning and training, 195. Of moulding up; of general management, &c. 196. Of watering, and of ripe fruit, 203. Of second crop, 198. Of paper lights, 199. Of third crop, 20Q.

#### SECTION XV.

#### OF ESCULENTS.

Their usefulness, 200. When to gather them; culture of alexander; artichoke, 201. Asparagus, 203.

Bean.

Bean, 206. Beet, 208. Boorcole, 209. Brocoli and Brussel sprout, 210. Cabbage, 211. Red cabbage, 212. Carrot, 212. Caulislower, 214. Celery, 216. Celeriac; chardon, and chou de milan, 218. Colewort and cucumber, 219. Endive, 220. Garlick; gourd; and horseradish, 221. Jerusalem artichoke; kidney bean, 222. Leek, 225. Lettuce, 226. Melon; Onion, 228. Parsley, parsnep, and pea, 230. Potatoe, 233. Pumpion, 237. Radish, 238. Salsafy, 240. Savoy; scorzonera; and sea cale, 241. Shalot; skirret; spinach, 243. Turnep, 244. French turnep; turnep cabbage, 245.

#### SECTION XVI.

#### OF HERBS, &c.

Culture of angelica; balm, 246. Basil; borage; buglos; burnet, 247. Camomile; capsicum; carraway; carduus benedictus; chervil; cives, 248. Clary; coriander; corn fallad; cress, 249. Dill; fennel; sinochio, 250. Hyssop; lavender, 251. Marigold; marjoram; mint, 252. Mustard; nasturtium, 253. Parsley; pennyroyal, 254. Purslane; rape; rampion; rocambole, 255. Rosemary; rue; sage; samphire, 256. Savory; smallage; scurvy-grass; sorrel, 257. Succory; tansey; tarragon; thyme, 251. Tomatum; Wormwood, 259.

#### SECTION XVII.

#### OF FRUITS.

Variety of forts, and difference in those of the same name, 260. Confusion in names; choice directed, 261. Care in planting, and of apples, 262. Of the apricot and berberry, 263. Cornel; cherry; chesnut; currant; sig; silberd; gooseberry, 264. Grape; medlar; mulberry, 265. Nectarine; peach; pear, 266. Of gathering pears, and keeping them, 267. Plum; quince, 268. Raspberry; service; strawberry; walnut, 269.

#### OF FLOWERS.

Of the classes, annuals, biennials and perennials, 270. Praise of flowers, 271. Of annuals in general, &c. 272. Culture of tender annuals, 273, &c. Of scoop-trowels and watering pots; of potting plants, 276. Of watering them, 277. Of potting hardy flowers; second sowing of tender annuals, 278. Of sowing the less tender forts, 279. &c. Of the hardy kinds, 280. Second fowing of hardy annuals, 282. Culture of biennials, 282. Of perennials, 283. The Dutch famous for producing new flowers. Directions for raising bulbous and tuberous roots, 284. Of raising fibrous rooted forts; general culture of bulbous and tuberous roots, 285. Of offsets; seasons for planting different forts, 286. Soil suitable, and depth at which to plant, 287. Disposition, distances and management, 288, &c. Of forwarding spring bulbs in water glasses, &c. Of stalk bulbs, 289. Of faving feed. Bulbs are yearly renewed. Propagation of flowering shrubs, 290. Of American forts. Particular use of the hand-glass, 291. A useful observation, 292.

#### SECTION XIX.

#### LISTS OF TREES, SHRUBS, AND FLOWERS.

Concerning them, 292. Time of flowering, colours, names, 293. Sorts; list of forest-trees, 294. Observations on ditto, 295. List of large deciduous ornamental trees, 297. Observations on ditto, 299. List of smaller deciduous ornamental trees, or large shrubs, 300. Observations on ditto, 302. List of the lowest deciduous trees, or shrubs, 303. Observations on ditto, 306. List of evergreen trees, 309. Observations on ditto, 311. List of evergreen shrubs, 312. Observations on ditto, 314. List of flowers—tender annuals, 316. Observations on ditto, 317. Less tender annuals, 320. Observations on ditto, 321. Hardy annuals, 325. Observations on ditto, 327. List of biennial slowers, 329. Observations on ditto, 330. List of sibrous

fibrous rooted perennials, 333. Observations on ditto, 339. List of bulbous, tuberous, and fleshy rooted perennials, 349. Observations on ditto, 352. Detached articles-auricula, 357. Carnation, 359. Geranium, 361. Pinks, 364. Polyanthus, 365. Tuberofe, 366.

#### SECTION XX.

#### A CALENDAR.

Of the general work of gardening, 368. January, the particular work of, 369. February, 371. March, 373. April 376. May, 379. June, 381. July, 384. August, 387. September, 390. October, 392. November, 395. December, 398. Close, 400.

TO PERSONAL THE

i ne grant Loud Basse's opinion of gardening, given in the north of the atle page, is certainly begin this and

#### THE PRAISE OF GARDENING.

IT is of importance to the welfare of any art, that I those whose taste inclines towards it, should have a good opinion of its utility, and competent notions of its principles. It is therefore the delign of the present section, to shew the degree of estimation that the art of Gardening is worthy of; and it is the object of the next, to affift in the acquiring that knowledge of Nature, upon which the art so much depends.

Not to enlarge upon the profits of gardening, its employments are certainly conducive to health of body, and peace of mind; and great indeed are the charms and recreations of a garden well stocked, and well managed by the hand, or under the direction of the owner himself: It at all times serves him as a source of

rational amusement, and honest satisfaction.

The praise of gardening, it is presumed, can hardly be too highly extolled; and, as this has been so well done by the best of men, and most respectable of writers, it may better answer the present purpose to produce their fentiments, than to attempt new ones.

What we admire, we praise; and when we praise, Advance it into notice, that its worth in the Acknowledged, others may admire it too. and H config. which does to all a rollingere,

N

The great Lord Bacon's opinion of gardening, given in the motto of the title page, is certainly both just and honourable. The agreeable Cowley speaks of his darling nature as enjoyed in a garden, thus:

When God did man to his own likeness make,
As much as clay, tho' of the purest kind,
(By the great potter's art resin'd)
Could the divine impression take,
He thought it sit to place him, where
A kind of heaven too did appear,
As far as earth could such a likeness bear;
That man no happiness might want,
Which earth to her first master could afford;
He did a garden for him plant,
By the quick hand of his omnipotent word;
As the chief help and joy of human life,
He gave him the first gift,—even before a wife.

And well he knew, what place would be agree, With INNOCENCE and with FELICITY.

And we elsewhere still feek for them in vain, If any part of either yet remain.

If any part of either we expect

This may our judgment in the search direct;

God the first garden made, and the first city,—Cain.

When Epicurus to the world had taught
That pleasure was the chiefest good,
(And was perhaps i'th'right, if rightly understood)
His life he to his doctrine brought,
And in a garden's shade, that sovereign pleasure
fought.

Whoever a true epicure would be, May there find cheap and wirtuous luxury.

Nor does this happy place only dispense
Such various pleasures to the sense,
Here bealth itself does live
That salt of life, which does to all a relish give,

d

Its standing pleasure, and intrinsic worth, The body's virtue, and the soul's good fortune, health.

Methinks I see great Disclesian walk
In the Salonian garden's noble shade,
Which by his own imperial hands was made:
I see him smile, methinks, as he does talk
With the ambassador, who came in vain
T'entice him to a throne again:
If I, my friends, said he, should to you show
All the delights which in these gardens grow,
'Tis likelier much that you should with me stay,
Than 'tis that you should carry me away:
And trust me not, my friends, if every day
I walk not here with more delight
Than ever after the most happy sight,
In triumph to the capitol I rod,
To thank the Gods, and to be thought myself a God.

Mr. Cowley's passion for retirement was indeed very strong; but might he not well say, "Is there not a cause?" He had been conversant in high and public life, and was very glad to leave

Those dangerous posts, where customs ill agree With virtuous rules, or found philosophy.

As one reason for his going out from Sodom (as he speaks) to his little Zoar, he asks,

Who that has reason and his smell, Would not among roses and jasmin dwell, Rather than all his spirits choak With exhalations of dirt and smoak; And all th' uncleanness which does drown In pestilential clouds a populous town.

Another poet (Clericus) retiring from town to a cottage and a garden, fays,

I strait

pre

I strait betook myself to trace the laws
Of nature, upwards to its fruitful cause;
And, digging mines of true philosophy,
The mystic stone I found, whose energy
Apply'd, transmutes some matter, some sublimes,
Drawing within my circle golden times.

Often amused with seats of gardening,
Delightful exercise, I work and sing!
And moving chearful seel not half my toil,
Like swains that whistle, while they plough the soil.
Should any disbelieve, I here invite
Such insidels to come, and trust their sight.

—Uncorrupt and happy days were those When Roman Consuls exercised their hoes; Whose leisure hours in country cares were spent, And whose diversions all were innocent. Oft their own labours furnish'd out their feast, And thus their fruits and fallads relish'd best.

ART OF GARDENING.

t

Mr. Evelyn, who had so great knowledge and experience in the way of gardening, speaks its praise in these words: Though the gardener's life be a laborious one, yet is it full of tranquillity and satisfaction. A condition surnished with the most innocent, laudable and purest of earthly selicities; and such as does cortainly make the nearest approaches to that blessed state, where only they enjoy all things without pains.

Mr. Addison says, I look upon the pleasure which we take in a garden, as one of the most innocent delights of human life. A garden was the habitation of our first parents before the fall. It is naturally apt to fill the mind with calmness and tranquillity, and to lay

all its turbulent passions at rest. It gives a great insight into the contrivance and wisdom of providence; and suggests innumerable subjects for meditation.

\* \* \* \* \*

Mr. Hervey, in his Meditations, on return from a walk, having entered the flower garden, and called it a beautiful spot, says, "Here nature always pleasing, every where lovely, appears with peculiar attractions. Yonder the feems dreffed in her desbabille; grand, but irregular. Here the calls in her hand-maid art; and thines in all the delicate ornaments, that the nicest cultivation can convey. Those are her common apartments where the lodges her ordinary guests: This is her cabinet of curiofities, where the entertains her intimate acquaintance. My eye shall often expatiate over those scenes of universal fertility: My feet shall sometimes brush through the thicket, or traverse the lawn, or stroll along the forest glade; but to this delightful retreat shall be my chief refort. - Thither will I make excursions, but here will I dwell."

On the Kitchen Garden Mr. H. observes, "Here those celebrated qualities are eminently united,—the utmost simplicity with the greatest neatness: none of the productions affect sinery. If it be pleasing to behold their orderly situations, and their modest beauties; how delightful to consider the advantages they yield! What a fund of choice accommodations here! What a source of wholesome dainties, and all for the enjoyment of man! Not one species of all this is a cumberer of the ground. Not a single plant but is good for food, or some way salutary. And with so beneficent an economy are the several periods of their ministration settled, that no portion of the year is lest destitute of such nourishing esculents as are best suited

bodies.—On! why should the possessor of so valuable a spot envy the condition of kings? Since he may

B 3 daily

ble

or-

te,

daily walk amidst rows of peaceable and obsequious subjects; every one of which tenders him some agreeable present, and pays him a willing tribute. Such as is most excellently adapted, both to supply his wants, and regale his taste; to surnish him at once with both plenty and pleasure."

From the amiable Comper something on this subject may be added. See the garden, in his Poem, emitted

the TASK.

O friendly to the best pusuits of man, Friendly to thought, to virtue and to peace, Domestic life in rural leisure pass'd.

Seenes formed for contemplation, and to nurse The growing feeds of wisdom; that suggest, By every pleasing image they present, Resections such as meliorate the heart, Compose the passions, and exalt the mind.

Oh! bleft seclusion from a jarring world, Which he, thus occupied, enjoys! Retreat Cannot indeed to guilty man restore Lost innocence, or cancel follies past, But it has peace, and much secures the mind From all assaults of evil, proving still A faithful barrier, not o'erleap'd with ease, By vicious custom raging uncontrous'd Abroad, and desolating poblic life.

The morning finds the felf-sequester'd man, Fresh for his task, intend what task he may.

—If the garden with its many cares, All well repaid, demand him, he attends The welcome call.

Had I the choice of sublunary good, What could I wish, that I possess not here?

Sir William Temple commended the employment and care of a garden as his settled choice, saying,—
For my own part, as the country life, and this part of

us

e-

as

ts,

th

क्ष

ed

of

it

it more particularly, were the inclination of my youth itself, so they are the pleasures of my age.

Le Pluche justly afferts,—Of all the employments in life, none is more simple, natural, and entertaining,

than the cultivation of plants.

Virgil of old, describes the happiness of a cultivator of the ground in gardening and planting, as equalling all the opulence of kings, in the ease, content, and freedom of his mind. This is one of the most assured truths; and happy are they who are free from the entanglements of artificial life, and not over-burthened

with honour and greatnefs.

Gardening leads to planting and farming, of which, collectively, Mr. Cowley prettily speaks.—It is one of the best natured delights of all others, for a man to look about him, and see nothing but the effects and improvements of his own art and diligence; to be always gathering of some fruits of it, and at the same time to behold others ripening, and others budding; to see all his fields and gardens covered with the beauteous creatures of his own industry; and to see, like God, that all his works are good.

Of a country life in general, Mr. C. says, "We are here among the vast and noble scenes of nature; where we walk in the light and open ways of the divine bounty, and where our senses are feasted with the clear

and genuine tafte of their objects."

# CONCERNING VEGETATION.

AS a good GARDEN affords much pleasure and profit, it deserves every attention; and certainly the cultivation of it cannot be too rationally pursued. It is therefore that a sketch of the Nature of Vegetation is here attempted; for the use of those who are unacquainted with the subject to affish them in the pursuit of gardening with understanding.

Let the ELEMENTS be first considered.

EARTH, as an element, considered in itself, appears not to serve to the support of man or beast. Though from it all things spring as from a common womb; yet independent of the other elements, or extraneous matter, it neither produces, nor affords, any thing like food. Affisted however by these, there is a combination of powers, the effects of which are equally beneficial and wonderful.

It has been pretty much an opinion, that the earth acts only as a receptacle for nutriment; and as a resting place, or means of supporting plants erectly; to imbibe rain, dews, air, &c. needing continually to be replenished by manures, or from the atmosphere. Indeed, it is not to be conceived, how the earth, considered as a solid, should pass through the capillary parts of plants. Experiments have proved, that the earth is very little, if at all exhausted, by the growth of plants, and consequently affords a presumption that plants are not fed by it.

There has been much controverly about the feet of plants. A respectable writer says, The saline, unctuous, and subtle slime, which the water separates from the coarse earth, and keeps in a dissolved state, is the principal nutriment of plants. And indeed, this is the opinion of others, who have treated the subject, and is justified by enquiries into the nature of the sap of plants, by decomposition:

Those who contend for an inherent power in earth to nourish plants, lay a stress upon the circumstance, that various earths have various qualities, fuited to different parts. But to this it may be faid, that the earth being more or less binding, or composed of differently constructed particles, occasions the parting with the food committed to it, the more or less freely, or altered according to its various modes of percolation,

or straining.

WATER appears to have much to do in the fubfistance of plants, for they consume a great deal; and either die, or are at a stand, when they are deprived of it, or at least of humidity from the air. It is proved, that feeds and plants, and in fhort all fubstances, consist chiefly of water, being reducible to liquids in a great degree. Thus some ancient philosophers maintained, that all things have their nourishment and growth from water.

Water (with respect to vegetation) has been defined to be, a mixed fluid, in which are all forts of particles proper for the composition of plants. But though feeds will germinate in water, they will not proceed to grow in it. Rooted trees however have been fet in water at the fpring, (as a rose) and put forth leaves fair, though pale; and it is well known, that many flips and branches of plants will strike root in water, readily: and gathered flowers not only keep fresh in

it, but increase in fize, and buds also open.

The

The natural state of water uninsuenced by heat is ice, and when very cold, it is too dense a study to pass through some of the capillary vessels of plants; yet a small degree of heat rarises it; and as its globules are capable of being infinitely divided by a proportionate heat; it is thus rendered fit to pass through the finest eanals. It mixes with the nutritive properties that are lodged in the earth, and is (at least) the vehicle of the food of plants. In this respect alone, it is most valuable. Without it, nothing could be elaborated in nature, no fermentation be wrought, and animals and plants would die of thirst!

AIR is found in a confiderable degree in water, in plants, and in fruits. It may be almost demonstrated (says one) that the vegetable nourishment is principally in the air: The tree Sedum lives and grows for years without earth or water.

How necessary this element of air is to man, the commonest observation evinces. Deprived of air, life is quickly lost, and in a depraved state of it, runs fast to sickness and death. Thus plants are found to sourish in a free and open air, and grow pale and languish in the contrary. But air is not only necessary for the leaves of plants to breathe in, but their roots require it: Plants will not do well if the soil is too much bound for the air to penetrate freely about them.

The fickliness of boused plants has been said to be owing greatly to want of motion. But the want of fresh air, is undoubtedly the chief cause; for pure air is fraught with animating principles, and by its attenuating and elastic properties, separates the gross juices, keeps the sap in motion, and the plants in health.

dir conveys to the organs of smelling, all those grateful scents, which plants, flowers and fruits produce, and we are greatly regaled, and refreshed by them. S

1

If it be asked, what oir is, and of what it consists? It may be answered, Particles of wet and dry bodies volatilized, and rendered elastic by fire. The air or atmosphere that surrounds our earth, contains a mixture of all the active volatile parts of the whole habitable world; that is, of all vegetables, minerals and animals. Whatever perspires, corrupts or exhales, impregnates the air; which, being acted upon by the solar fire, produces within itself, all forts of chemical operations, dispenses again those salts and spirits in new generations, which it had received from putre-factions.

FIRE, as it operates from the prime body of it the sun, gives life and energy to all, completing the process of nature. There is no existing without it. Its total absence would presently bring all animation to the coldness of death!

The fun by its warmth (conveyed by the air) fets forward that fermentation in the earth, and gives that spirit to plants, which effects growth, and concocts

their juices to make them fruitful.

Libore ale marche for

It is by the rarefaction of the air and juices contained in the roots, and all the parts of a plant, that motion and expansion are given to it; and by its ascending force, pushes into buds, leaves, flowers and fruits; sending off superfluous and excrementitious moisture into the atmosphere, thus giving us the scents peculiar to each. That the sun does this, is evident from what is experienced in artisticial warmth, hurrying on the growth of plants, which is ever proportionate to the heat applied, provided there is a proper supply of moisture.

Without the vivifying fun, the other elements would be inactive matter, and "no longer would the fig-tree blossom, nor fruit be in the vine: The labour of the olive would fail, and the fields yield no meat." The operative power of the sun reaches the deepest recesses, to beds of metals, and to " the place of Sapphires; and there is nothing hid from the heat thereof."

What bleffings does this bounteous planet pour
On the glad heart of man, when rolling round
His azure road, he scatters as he flies,
To warm his raptur'd bosom, light and joy!

NEWCOMB.

The sun is the fountain of LIGHT. This glorious object of creation, as a luminary, gives chearfulness both in nature and appearance to all things: If light is not so necessary to existence as heat, life would yet be miserable without it.

As to vegetation, we may observe, without light plants get always sickly, and would not exist long if deprived of it. Light, philosophically considered, is half their nourishment. All plants turn to the light as to a powerful attraction, or, as if conscious how necessary it is to their existence. Light at the same time that it heats, doth wonderfully rarify and raise the same with the same w

The physical properties of that etherial substance, which is so subtle and pervading as light, we may well believe to be various and wonderful, though inconceivable.

Behold the light emitted from the sun,
What more familiar, and what more unknown?
While by its spreading radiance it reveals
All nature's face, it still itself conceals.
How swift th' effulgent emanations fly
'Thro' the blue gulph of interposing sky!
Millions of miles, so rapid is their race
To cheer the earth, they in few moments pass.

Amazing

Amazing progress that its utmost stretch, and a sunt What human mind can this swift motion reach? BLACK MORE.

How impressively are we taught to value the bleffing of light, by a view of day-break in a fine summer's

The hour of morn returns, Unbars the gates of light, and opens wide A prospect to the eye, which now unfolds Ten thousand beauteous scenes which lay conceal'd Before in darkness: now the radiant heavens Glitter with azure pav'd, with roses strew'd. With lively verdure each green plain array'd, Each flower puts on a glow of richest hue; The wide creation now is feen adorned In all her rich attire and beauties bloom, View'd by each wand'ring eye with raptur'd joy! All the rich pomp which theatres display Their shining ornaments, the lustres hung In the proud courts and palaces of kings, Lose their diminished light, and die away, Whene'er the fun unfolds his radiant beams!

From this view of the elements it appears, that their offices are mutual, and that there is a barmony of them, necessary to the welfare of plants, in a view to which art may sometimes affist nature. It is for this end that what is faid of them here is advanced, that the young gardener may convert to use his entertainment.

Having feen a little into the nature of the ELE-MENTS, as they relate to the existence of plants, let us proceed to consider the plants themselves. Their structure has been examined by the greatest geniuses, and though able, (perhaps) to determine little of Nature's

ture's laws, yet has the pleasure and satisfaction they have reaped repaid them their trouble. Though after all our researches, we are finally led to this conclusion, that God's works, like his ways, are "past finding out;" yet if there is any satisfaction in knowledge, or any consolation in piety, these gratifications are to be sought in, and will be reaped from attentive and modest enquiries into Nature. "The works of the Lord are great, sought out of all them that have pleasure therein."

Nature is nothing but the art of GoD; a bright display of that wisdom, which demands an eternal tribute of wonder and worship.

The notions which arise from Nature's light ? As well adorn the mind as guide her right, Enlarge her compass, and improve her fight. These ne'er the breast with vain ambition fire, But banish pride, and modest thoughts inspire. By her informed we bleft religion learn, Its glorious object by her aid discern. The rolling worlds around us we furvey, Th' alternate fov'reigns of the night and day; View the wide earth adorn'd with hills and woods, Rich in her herds, and fertile in her floods. Walk through the deep apartments of the main, Ascend the air to visit clouds and rain: And while we ravish'd gaze in Nature's face, Remark her order, and her motions trace. The long coherent chain of things we find Leads to a cause SUPREME, a wife creating mind. BLACK MORE.

SEEDS of plants stand first to be considered, and they are truly wonderful. What large plants from seeds no bigger than a grain of sand? What a stately oak from a little acorn?

The

re

1

e

t

e

The feeds of fern, which by prolific heat, Cheer'd and unfolded, form a plant so great; Are less a thousand times than what the eye Can unaffifted by the tube descry.

BLACKMORE.

Seeds contain in embryo (or miniature) the plant they are to produce, in all its parts, which they have preserved from age to age, seeds producing plants, and

plants feeds, &c.

They are covered with coats that are finely and closely wrought, the better to keep the moisture of the earth from coming in too suddenly upon the lobes, or the little plant, which might occasion their rotting, and we find that almost every fort of seed, by means of these coverings, must remain different lengths of time in the earth, before they begin to germinate. Some will not spring in the natural ground till the second year after they are buried, while others will begin to shoot in three days after sowing. This is owing to their requiring different degrees of moisture, heat and air, to make them germinate; i. e. bring them into a state of fermentation.

The fubstance of seeds appears to be spent first in feeding the radicle, and then in the nourishment of the two first, or feed leaves, which are commonly of a different size, shape and substance from the proper leaves of the plant: From between these comes a shoot bearing the true leaves. The lobes (or substance) of seed, consist of a farinous nutriment, adapted to the infant state of the plant, when softened and dissolved by the moisture of the earth, which extends and unfolds the young plant (or plumule) in the same manner, as the nourishing juice in the eggs of animals hatches their embryo. The seed leaves therefore contain a sugary juice, which is evident from insects so greedily biting them, and their pleasant taste in sallads, as those of turnips, cabbages, &c. They

are thick and succulent, calculated to imbibe air and moisture from the atmosphere, for the support of the tender plant, that might otherwise suffer by drought: for it must proceed in growth, or it would quickly die. When the radicle has struck downwards, the office of the seed is evidently to nourish these leaves, as is seen by the seed coming above the ground with them, exhausted of its substance—a mere shell sticking to the top of the leaves.

But some plants have no seed leaves properly so called, as corn; which has therefore been deemed by

fome, not firially a feed, but a bud, or bulb.

It has been doubted whether all plants have feed, because fome forts have not been observed to produce it. To conclude that they have, is however more agreeable to the uniformity of the divine procedure, and altogether to reason.

Seed may be so small as not to be discerned with the help of convex glasses, as we know there are many not discernible without them; and with this minuteness, it may be extremely sugacious by its slight adhe-

fion to the plant.

The truth is, God originally ordained that plants. should proceed from feed, and they do, (Gen. i. 2.) It was long faid, that fern bare no feed; but this is a demonstrable mistake. That Mushrooms produce feed, we need not doubt. Many of the mosses are fosmall in the state of plants, that the microscope only can discover their flowers, and even in some, the plants themselves are but barely thus discernible. A great variety of feeds are wafted about continually in the air, and produce their kind, whenever they light upon a proper matrix. Whatever has been objected there appears good ground for believing, that there is no natural production, either in the vegetable or animal kingdom, but what comes from the feed, or egg of fome parent. As.

As to certain plants appearing where none were before, we know that some seeds will keep many years, when deep buried, and being afterwards brought to the furface, have vegetated, as the wild mustard, &c. Befides the wind carrying some forts of feeds to a confiderable distance, birds also drop a great many, so that plantations of oaks, &c. have fprung up by means of crows carrying the acorns, and dropping them in

cracked ground.

PLANTS follow feed, and we find them proceeding in a fleady unceasing progression towards maturity, to their destined end, i. e. production of the like, from which they sprung (seed) to preserve the species. And the economy of nature is so regular, that a certain portion of time is invariably kept (allowing for accidental circumstances) for this business. So certainly does Nature pursue her end in all respects, that the identical species is always preserved, as to the distinguishing properties of each, though the foils in which feeds are fown are fo various. Altogether under the fame circumstances are produced the sweet smelling flower, the nourishing corn, and the poisonous plant, though differing much in strength, in figure, and other particulars.

The juices in the vessels of plants undergo (according to their conformation) different fermentations, and thus become altered; in which chemistry of nature,

its powers and refults are wonderfully exact.

Peculiar pores peculiar juice receive. To this deny, to that admittance give. Hence various trees their various fruits produce, Some for delightful tafte, and some for use, Hence sprouting plants enrich the plain and wood, For physic some, and some defign'd for food. Hence fragrant flow'rs with different colours dy'd, On imiling meads unfold their gaudy pride! constitut has ano, were in before Black more of

if we confider them as summining appointment

from

The ROOTS of plants are to keep them fixed in the earth and to draw food from it; which they do (chiefly at least) by their ends which have been therefore called mouths: In general they affect an horizontal growth, for the benefit of the fun and air, and never descend above a certain depth from the surface.

By means of the root, nourishment proceeds through the pipes and capillary conduits of plants, continually from the earth, and by the action of the fun and air, circulates, rarifies, and distributes itself. This juicy food, fwells the little bags, or cells (of which the fubstance of plants is composed) and following the different modifications thereof, filtrates athwart the parts. For example. That which is most pure and fine, serves to nourish the flowers and fruits; that which is not supplies the branches, and leaves, and roots; the most gross and earthy serves for the bark; and the most oily is for gum and rofin. Just the same as we find it in animals, where the food they receive into the stomach. passes afterwards into the blood, circulates into the vesfels, and pursuing its different degrees of attenuation, ferves to nourish the different parts of the body.

The STEMS or trunks of plants are for the support of the head, and to convey juices from the roots upwards for the leaves, branches, &c. and are composed (as the roots) of bladders, and various conduits for air, sap, &c. perpendicular, spiral, and horizontal from the pith to the bark. These vessels may be somewhat seen with the naked eye, as in slices of the young shoots of nut, apple tree, and vine, but very evidently by a microscope. It is observable, that some plants which are weak and pipy have knots at proper distances to strengthen them, and others have claspers to hold them up; while others are robust enough in stem to

brave the fury of a tempest.

The LEAVES of plants are very variously, but beautifully constructed in their form and substance; and if we consider them as attracting nourishment II.

from the root and the atmosphere, and as perspiring and respiring, they are more than commonly thought, essential to vegetation; and so we find that if the stems, or branches of a plant, are considerably deprived of them, it becomes stunted and diseased, and if any fruit appear, it proceeds slowly in growth, and is ill slavoured. The quantity of nutriment which a plant derives from the earth, is in proportion to the number and size of its leaves; thus that they may uninterruptedly perform their offices, they are distributed in a very distinct and separate mode.

The under and upper part of leaves are different, and have separate offices; the under is rough and porous, as if adapted to imbibe the rising moisture of night dews; and the upper, or closer, to exclude the grosser parts of the atmosphere, and to imbibe some finer food, as to "draw the live ether." Thus leaves will not endure to be reversed, as is seen by the certain and quick return to their right position, when forced from it, and till this is effected, they perform not the proper

That the glossy furface of leaves have an intimate connection with the light is evident, as they rise and fall (in a degree, some plants more and others less) as the sun moves. If they are turned from the light they twist themselves towards it, as if they had enjoyment, and were conscious of the benefit.—The curious will meet with gratification relative to this subject, by confulting Hill's Tract On the Sleep of Plants; or his gardening for October:—a large solio.

One of the offices of leaves, seems to be, to subtilize, and give more spirit to the abundance of nourishing sap, and to convey it to the little buds at their soot stalk, to whose welfare they are essential.

If the texture of the leaves be scrutinized, they are found curiously ramified; the ribs and fibres of each seeming much like a spreading plant. The ramifications hold a close communication with each other;

for that the principal rib sends out lateral ones less strong, and they again an infinite number of sine ones in all directions; and these are vessels of two kinds, viz. for sap and air. As leaves throw off a great deal of excrementatious, so do they imbibe a great deal of nutritious moisture, as is evident from the general refreshments received from dews. Yet we are not to conclude, that the other parts of plants do not the same in a less degree; and the rough bark of the trees, and the outer vessels, are well calculated to detain moisture, to convey to other parts.

The BRANCHES of plants come next to be confidered. How beautifully do they spread, and how uniformly do they proceed, keeping up precisely the same mode of growth, one from another throughout the whole; till the head of the plant, or tree, attains its customary size, and own peculiar form; which if it has grown with native liberty, proves always of an

agreeable symmetry.

The texture of branches consists of the same kind of vessels as the stem, or trunk; but here it may be observed, that there is yet a specific difference in the vessels of the various parts, as is concluded from their affording juices of a different slavour and essure in the bark, wood, leaves, slowers and seeds; so that from the same plant are extracted medical properties

Buds are like seeds, as they contain the suture growth of branches and fruit in miniature, so that for instance, in the buds of a currant-tree may be discovered (by a microscope) even before winter, the woody branch, and the bunches of fruit. The suture fruit also has been viewed in the bud of a vine. In the short buds of pears, which appear at Midsummer, an indifferent microscope will shew the blossoms designed for the April sollowing. The buds of a Mezerian being examined at Midsummer, had the blossoms discovered

un ed

C

ed

covered in them, though the time of their blow is not

till February.

Thus it appears, that the leaves, blossoms, fruit, and branches, on all trees, are formed the year before; and so their fruitfulness in the year they bear, is no otherwise the consequence of that season, than that nature has gone without any destructive check in her progress, and particularly at the time of flowering, when many blossoms are destroyed by inclement weather, and by wet only as much as any thing.

The FLOWERS of plants have not yet been particularly noticed, but of them fomething must, and much might, be said.

Go, mark the matchless workings of the power That shuts within the seed the suture sower; Bids these in elegance of form excel, In colour these, and these delight the smell; Sends nature forth, the daughter of the skies, To dance on earth, and charm all human eyes.

COWPER.

Flowers have a general structure in substance, similar to the other parts of plants, as to vessels for sap, air, &c. only are so much the more exquisitely formed, as the leaves are of so delicate a texture. They are formed in the bud while in the pith, and so

confequently are the fruit and feed.

The flowers of many proceed from a bud, or knot, the leaves or parts of which do first cover the flower contained therein, whilst it is yet unable to bear the inconveniencies of the weather, and defend it from the same; and after the flower is blown, they keep up its leaves, that they may not hang consusedly together, but regularly represent their beauties to the eyes of the beholders: This is exemplified in the carnation. Those that have a cup to sustain their leaves,

are

4

-1

f

F

a

t

are weak in their texture, and so need this support; but those that are strong have it not, as lillies, tulips, &c. Those that have no cup are, however, covered in the bud by some sheath, or tegument, to preserve them, while young, and yet too tender to be exposed.

The leaves of flowers protect and conceal the feed of those that bear it, where nature secretly works to the great end of propagation. The seed is the natural offspring of the flower, and when this is once well formed, the several parts of the flower dwindle and disappear. So that while we are admiring the colour, shape, and perfume of these delightful companions of our walks, they are kindly engaged to provide the means of perpetuating pleasure to us.

The care which the AUTHOR of nature has taken to preferve the feed of plants, by the flower leaves which contain the embryo, as in a matrix, is admirable! The flowers themselves come not forth till the season suits their particular temperament, many are hid till then under the coverture of the earth, and those that dare to continue above ground all the year, have yet their gems carefully locked up, and thus their succession and their fruits are secured to us.

The flowers of plants have a remarkable property, when they begin to unfold, and the feed is yet young and tender; they observe the course of the weather, day and night, opening and shutting their flowers accordingly. There is also a property of some flower plants, twining round solid bodies, or fixing themselves to them by classers, laying fast hold of what may be in their way. Flowers have many admirable properties and parts, that might be considered distinctly, if it were designed to speak of them botanically.

From flowers (of which every month in the year has its beauties) we eventually gratify the palate, by a valuable nectar, and from many we immediately reap agreeable odours; but it is for their colour to de-

light

light the eye, that we chiefly cultivate them; and in this respect we may exclaim with the poet,

Who can paint like nature? Can imagination boaft Amidst its gay creation, hues like her's? Or can it mix them with that matchless skill, And lose them in each other, as appears In every bud that blows?-

THOMSON.

But not only the colours delight the eye, the forms of flowers are objects of admiration. The leaves of the plants (not to mention the shades of their green and variegations of other colours) are of various symmetry, fome plain, others indented, some hard, some soft, fmooth, hairy, &c. Flowers are composed, some of only one, others of feveral and numerous leaves. Here it appears like a large vessel gracefully opening. There it forms some grotesque figure, in imitation of a muzzle, head piece, or cowl. Here it is a butterfly, a star, a crown, a radiant sun. Some are scattered on the plant without any art; others compose nosegays, globes, tufts of feathers, garlands, pyramids, &c .-The feeds of plants are as variously formed as their leaves and flowers.

The following description of Flora's festival and the month of May, may very well finish the notice

here taken of flowers.

The good Postbumius chose the first of May, To FLOR's facred, and observed the day With holy rural rites, that won by prayer She might diffuse her blessing o'er the year; His homely neighbourhood in green privet dress'd, With strict devotion keep the cheerful feast, And crowned with chaplets, to fair Flora bring The first and freshest beauties of the spring. Gardens are now with choice perfumes supplied, By these and thousand nameless sweets beside:

Tis

'Tis the gay month of all the youthful year,
When nature smiles serene, and calm the air;
In the tall grass the soft Favonius plays,
And nightingales repeat their tuneful lays;
The flocks too frisking o'er the flowry vale,
With eager joy the cheerful season hail.

RAPIN.

In considering the works of nature, it is hardly possible but to feel both concern and indignation at the folly of Atheism, and the absurdity of the Atomic philosophy. Both have been well exposed by many writers, and completely so by Sir Richard Blackmore, in his Poem on the Creation; from which though some extracts have been already made, let the following be added,

How dark is human reason sound,
How vain the man with wit and learning crown'd;
How seeble all his strength when he essays
To trace dark nature, and detect her ways,
Unless he calls its AUTHOR to his aid
Who ev'ry secret spring of motion laid;
Who over all his wond'rous works presides,
And to their useful ends their causes guides?
These paths in vain are by inquiries trod,
There's no philosophy without a GOD.
Th' ETERNAL MIND's existence we sustain.
By proofs so full, by evidence so plain,
That none of all the sciences have shewn
Such demonstration of the truths they own.

Good heaven! that men who yaunt difcerning fight,
And arrogant from wifdom's diffant height,
Look down on vulgar mortals who revere
A CAUSE SUPREME, should their proud building
rear,
Without one prop the pond'rous pile to bear!

Ye friends of Epicurus look around,
All nature view with marks of prudence crown'd.

Mind the wife ends which proper means promote, See how the different parts for different use are wrought; Contemplate all this conduct and design, Then own, and praise, the ARTIFICER DIVINE!

For several of the foregoing observations, and some of the padlages on vegetation, Mr. M. thinks it proper to acknowledge, that he is indebted to the excellent Mr. Derham, and others.

#### OF THE FORMATION OF A GARDEN.

THE garden here meant, is one where vegetables, fruits and flowers are cultivated under the fame inclosure. Considering the profit and pleasure to be reaped from a good garden, it is certainly an object of some consequence to the comfort of human life. It will not, therefore, be prudent in any one who has a garden to form, to be niggardly, either in allotting ground for it, or in expence and trouble to prepare and lay it out in the best manuer.

The agreeable work of making a new garden can happen to few; and when it does, foil, fituation, and space, all favourable, are happy circumstances not always at command: It often indeed happens, however, that pieces of ground are taken into use as additions, and some judgment should be exercised in the choice,

that the business may be well done.

To

C

fi

do.

To help towards resolving on the quantity of ground it may be prudent to cultivate as a garden, a general idea may be given in observing, that an acre with wall-trees, hot beds, pots, &c. will furnish employment for a man, who at some busy times will need affishance. The size of the garden should, however, be proportioned to the house, as to the number of inhabitants it does, or may contain. This is naturally dictated; but yet, it is better to have too much ground allotted than too little, and there is nothing monstrous in a large garden annexed to a small house.

Some families use sew, others many vegetables, and it makes a great difference whether the owner is curious to have a long season of the same production, or is content to have a supply only at the more common times. But to give some rule for the quantity of ground to be laid out, a family of sour persons (exclusive of servants) may have a rood of good working

open ground, and fo in proportion.

But if possible, let the garden be rather extensive according to the family; for then, a useful sprinkling of fruit trees can be planted in it, which may be expected to do well, under the common culture of the ground about them; a good portion of it also may be allotted for that agreeable fruit the strawberry in all its varieties; and the very disagreeable circumstance of being at any time short of vegetables, may be avoided. It should be considered also, that artichokes. asparagus, and a long succession of peas and beans, require a good deal of ground. Hot-beds will also take up much room, if any thing considerable be done in the way of raising eucumbers, melons, slowers, &c.

The situation of a garden should be dry, but rather low than high, and as sheltered as can be from the North and East winds. These points of the compass, should be guarded against by high and good sences; by a wall of at least ten seet high; lower walls do not answer so well for fruit-trees, though one of eight may

not nay do. do. A garden should be so situated, to be as much warmer as possible, than the general temper of the air is without, or ought to be made warmer by the ring, and subdivision sences: This advantage is essential to the expectation we have from a garden lo-

cally confidered.

As to trees planted without the wall, to break the wind, it is not to be expected to reap much good this way, except from fomething more than a fingle row; i. e. a plantation. Yet the fall of the leaves by the autumnal winds is troublesome, and a high wall is therefore adviseable. Spruce firs have been used in close shorn hedges; which as evergreens, are proper enough to plant for a screen in a single row, though not very near to the wall; but the best evergreens for this purpose are the evergreen oak, and the cork tree. The witch elm, planted close, grows quick, and has a pretty fummer appearance behind a wall; but is of little use then, as a screen, except to the West; where still, it may shade too much (if planted near) as it mounts high: In a dry hungry foil, the beech also is very proper; and both bear cutting. The great maple, commonly called the fycamore, is handsome, of quick growth, and being fit to stand the rudest blasts, will protect a garden well in a very exposed fituation: the wind to be chiefly guarded against as to strength, in most places, being the westerly.

The form of a garden, may be a square, but an oblong is to be preserved; and the area rather a level; or if there be any slope, it should be southward, a point either to the East, or West not much signifying, but not to the North, if it can be avoided, because crops come in late, and plants do not stand the winter so well in such a situation. A garden with a northern aspect, has, however, its advantages, being cooler for some summer productions, as strawberries, spring sown caulistawers, &c. and therefore to have a little ground

2

tooner

under cultivation, so situated, is desirable; especially

for late faccession crops.

The foil that fuits general cultivation best, is a loam; rather the red than the black; but there are good foils of various colours, and this must be as it happens: The worst soil is a cold heavy clay, and the next a light fand; a moderate clay, however, is better than a very light foil, though not fo pleasant to work. If the foil is not good; i. e. too poor, too ftrong, or too light, it is to be carefully improved without delay. first, at least, be thoroughly broke, and cleaned of all rubbish, to a regular level depth at bottom as well as top, fo as to give full eighteen inches of working mould, if the good foil will admit of it; none that is bad should be thrown up for use, but rather moved This rule of bottom levelling, is particularly necessary when there is clay below, as it will fecretly hold up wet, which should not stand in any part of the garden. When a piece of ground is cleared of roots, weeds, stones, &c. it would be of advantage, to have the whole thrown into two feet wide trenches, and lay The ground thus as long as conveniently may be. cannot be too well prepared; for when this business is not performed to the bottom at first, it is often neglected, and is not conveniently done afterwards; and so it happens, that barely a spade's depth (or less) is too often thought sufficient to go on with. There is this great advantage of a deep staple, that in the cultivation of it, the bottom may be brought to the top every other year, by double trenching, and being thus renewed, less dung will do, and sweeter vegetables be grown: Tap-rooted things as carrots and parsnips require a good depth of foil.

The aspect of the wall designed for the best fruits, may be full South, or rather inclining to the East, by which it will catch the sun's rays at it's rise, the cold night dews be earlier and more gently dissipated, and the scorching rays of the asternoon summer's sun are

fooner off. By thus having the walls of a garden not directly to the four points, the North wall is greatly

advantaged, by having more fun.

The barder next this wall should be of very good earth, about two feet deep, riling a little towards the wall. A free moderate loam, or some fresh maiden foil, not too light, is necessary; and it it is not naturally there, let no trouble be spared to procure it, if it can be had, so as to make all the borders promising good; and in order to this, if manure is necellary, let it rather be that of rotted vegetables, or turf with a fmall quantity of wood aftes, or a less of foot, or falt; for the roots of fruit-trees should not meet with much dung, at least of barfes; that of cases is the best, or that of sheep or bogs, will do, well-rotted, and well mixed, &c. being worked in the borders, as long as possible before the trees are to be planted. Let the holes be some time opened beforehand, that they may be improved by exposure to the atmosphere. Thus due care will be taken, and all things ready to go about the work of planting properly.

The borders for peaches, &c. cannot be too wide, for in a few years the roots will spread a considerable way; and that they may do it without impediment of rubbish in the walks, and without meeting with a bad soil, is of the greatest consequence to the future health

and fruitfulness of the trees.

If a garden is large and square, a second South wall, running down the middle of it would be very useful; and so, is large and long, a cross wall or two might be adopted, as giving opportunity for the cultivation of more trained fruit trees; and if there is any idea of forcing fruits, these intersecting walls, ranging East and West, are proper for it (as situated within the ring sence) furnished with slues, &c.

The best fruit border being prepared for peaches, nectarines and apricots, or vines and sigs, the trees should take their residence there (if the leaf is falling) about If the middle of *December* be past, *February* is then the time, though some gardeners plant all winter, if the weather is open enough at the time to work the ground. *March* may do, or even [upon a pinch] the

beginning of April.

Wall-trees should not be older than two years from grafting, or budding. Much disappointment has been the consequence of planting old trained trees, through their being accustomed (perhaps) to a contrary soil, or by damage done the roots in taking the trees up; and thus, instead of saving time, it has frequently been lost, being obliged, (after years) to be replaced with young ones. But if trained trees are to be made use of, let them be planted as early, and with as full roots as possible, and in a right good soil. Except in fine situations, as to sun, shelter, and climate, never plant early and late peaches, as the first may be cut off, and the latter not ripen: October peaches are generally

poor fruit North of London.

The distance to plant, should be about eight or nine inches from the wall, and let apricots, peaches, and nectarines be twenty feet afunder, more or less, according to the height of the wall; though for the small early forts fifteen or fixteen feet will do. As the larger apricots, however, grow freely, and do not well endure the knife, they ought to have twenty-five feet allowed them: This is for a wall of nine or ten feet high; if higher, the distance may be less, and if lower, the contrary. This room may feem (to fome) too great; but when trees are planted in too confined a space, after a few years it is troublesome to keep them pruned within bounds; and the cutting they must have, makes them run to wood, and thus to become less fruitful. Fig.trees require as much room as the apricot, or rather more, as they grow freely, and are to extend without shortening. Though other trees are best planted in October, the Fig should not be till March. The

The intermediate spaces between peaches, nectarines, and apricots, may have a vine, a dwarf-cherry, or currant, or goofeherry tree, of the early forts, as the smooth green and imall red, to come in early; and improved in the beauty, fize, and flavour of their fruit, by the But wherefoever grapes can advantage of fituation. be expected to ripen, there let a young plant, or cutting, be fet, though the space be confined; for the vine (freely as it shoots) bears the knife well to keep it within bounds. If the wall be high, the cherry, or plum, may be half-standards, which being after a while kept above, will be more out of the way of the principal trees: though dwarfs may be trained to as not to interfere. Some have planted half-standards of the fame kind of fruit as the dwarfs: but which ever way is used, let the intermediate trees be pruned away below in good time, in order to accommodate the prin-The better cipals freely as they mount and extend. way however is, when the wall is tolerably covered, to extirpate the intermediate trees, as (when large) they impoverish the border, and too much rob the principals of nutriment: If taken up well, in season, and pruned properly, they may be planted elsewhere. Something merely ornamental may occupy the vacancies also, as some double blossomed fruit tree, passion tree, roses, &c. or in a fine situation, a pomegranate; any of which may be removed when their room is wanted. See fection vill. On planting.

Plums, cherries, and pears, may occupy the other walls, the two former at about fifteen, or it may be twenty feet asunder. Cherries, except the Morella, will not do well in a full North aspect; but any sort of plum (rather a late one) and summer pears, and also nut trees will, if you chuse to train them. There should always be some currants and gooseberries in an E. and N. situation, at the distance of eight feet, where they will be easily matted, (when ripe) to come in late, as October, November, or perhaps December. Pear trees

C 4

of free growth are hardly to be kept within tolerable compass on low walls; but if attempted, should have at least thirty feet allowed them. The best forts of winter pears deserve a southerly wall to ripen them well, and improve them in fize and slavour: The gable end of a house is well adapted for a pear tree, as it affords room which they require. Apples may do on a wall, (and if any on a good wall, let it be the golden pippin) yet the practice is seldom adopted: The same may be said of mulberries, though they come to bearing much sooner against a wall; but they need not have a South aspect, indeed it has been afferted, that they do the best in a North one. For surnithing walls, chuse trees of moderate wood, rather than strong, young, well rooted, clean, and healthy.

When the planting of a garden is finished, it will be a good way to have a plan of it taken, with the names of every peculiar tree marked thereon, in their place, to be assured of the forts when they come to bear. Some have the names of the trees painted on boards, and placed behind them, to which if added the time of ripening (fixed late enough) it would tend to

prevent a premature plucking by vifitors, &c.

Here it may be observed, that if any evergreen hedges are defired, in or about the garden, yew, box, alaternus, celastras, phillyrea, and pyracantha, may be kept low, and clipped in form, if so defired: In addition to which, if a few roses were intermixed, it would have a pretty effect. A deciduous hedge for subdivision, or screen, &c. may be made of elms or limes, setting the larger plants at five feet asunder, and a smaller one between. Or an ordinary sence, or subdivision, may be quickly formed of elder cuttings, stuck in at two feet asunder, which may be kept cut within bounds.

The walks come next under confideration, and they are to be begun from the best wall; the border of which being regularly levelled and settled, the walk is to be governed by it. A wide border next the South (as was said)

faid) is best for the trees, and moreover for the many uses that may be made of it for the smaller early, or late tender esculents, and a sew early cauliflowers. For the sake of a pleasant sheltered walk, to have the South border narrow may be desirable; but on no account let it be within six seet. Take care that this walk is not sunk too much, and that it have a bottom of good earth, as deep as where the trees are planted. Let the body of gravel be thin, and then the roots of the trees will be admitted to run properly under the walk, and find wholesome nourishment; where if they were stopped by rubbish, they would be apt to canker, and irrecoverably disease the tree.

The number and breadth of the walks must in a measure be determined by the quantity of allotted ground; exceeding in these particulars where there is room. But better be sew and wide walks, than many and contracted. If the garden is small, one good walk all round is sufficient; and if long and narrow, the cross walks should not be many: six, or eight feet, is

not too wide for a moderate fized garden.

If the grounds be laid out in Autumn, leave the walks alone till Spring, when the earth will be settled. Gravel laid towards Winter would be disturbed by the frost, and the necessary work about the quarters and borders. But whenever made, the garden ought to be first carefully brought to an exact level; then the walks should be stumpt, keeping the tops of the stumps very level (as guides) to the true pitch of the quarters by a light line, made of good hemp, that will bear pulling tight. Proceed to take the earth out of the alleys about eight inches deep, which may be thrown towards the middle of the quarters, to give them a small convexity, which makes them look well.

Rake the bottom of the walk level, and lay the gravel to within two inches of the top of the stumps. The gravel will fettle a little, but the walks should always be about three or four inches at their edge,

C 5

below

below the quarters, or these will have a flat, and so a mean appearance.

If Edgings are to be made, in order to separate between the earth and gravel, especially if of stone, or wood, or box, they should be done first, and they will

be a good rule to lay the walks by.

If plenty of Gravel, lay it moderately fine: if scarce, fome small stones, or rubbish of any kind, may be laid in first, and rammed down level with a broad rammer; but do not spare for a little expence, if gravel can be had, as a thick coat of fine gravel, will bear relaying, or turning over, to refresh it occasionally in the spring. As the gravel is laid, let the operator neatly rake the larger parts down to the bottom leaving a fine surface, in a small degree convex, i. e. just barely sufficient to throw off wet: walks that lie high in the middle, are unpleasant to both eye and feet, and cannot be so well rolled, and kept in order.

When deep walks of gravel are defigned, for the fake of the mould dug out of the alleys, it should be forborne, and laid thin, if any trees are defigned to be planted near the edge; for if the roots of trees have not a good soil to strike into, when they reach the walks they will not (as has been observed) prosper. In laying gravel very thick, it is a good way to do it at two courses; the first of which may be rough as it comes from the pit, yet still raking the larger parts down, and then ramming or treading it; and the last

course should be of all screened materials.

It is best to lay a few yards of gravel only at a time, before ramming or treading; after which it may be necessary to go over it with a fine iron rake, tooth and back; and then a whole walk being finished, it should be repeatedly pressed with a moderately heavy soller; and again after the next rain that falls: so will the walks become nicely level and firm, in which their excellence consists.

Grass Walks may do where gravel is scarce; but the latter is so clearly preserable, that except for a little variety in large gardens where there are many walks, they will hardly be made choice of. They are troublesome to keep in order, and if much used are apt to get bare, and out of level, especially when narrow; they are also frequently damp to the seet.

Canomile, has been used also to form green or carpet walks, planting it in sets about nine or ten inches asunder; which naturally spreading, the runners are fixed

by walking on them, or rolling.

Sand may be adopted for walks, and there is a binding fort of it, that does very well; but lay not any of it too thick, as it is the less firm for it. Drift sand is

a good substitute for gravel.

Coal Ashes strewed thinly in the alleys are better than nothing, as they at least serve to keep the seet dry and clean. If the garden be a strong soil, these ashes (when worn down) may be thrown out of the walks, with a little of the earth, and will prove a good manure for the quarters.

Sea Shells make very good walks.

All trees designed to be planted, are to be thought of before winter. Those of the wall have been spoken of; and as to standards they must have a fair depth of good soil (not very dungy) to grow in, for it should be remembered, that tree roots in a garden are prevented from running over the surface, as they do in an undisturbed orchard. It is necessary that some caution should be used not to dig the ground too near, and too deep about garden trees; lest loosening the roots, they should not be able to stand the wind; and because the nearer the surface any root grows, the more, and choicer fruit, the tree bears.

But the fewer flandard trees in a garden the better, as they take up much room, and by their shade prevent the proper growth of vegetables that are any thing near them: so that if a garden is small, there should.

6 . be

be no trees except those of the wall. The case is different where there is ample room; and the blossoms of fruit trees (apples particularly) are so delightful, that if they produced nothing for the palate, there would be a sufficient inducement to plant them for ornament; but let them be dwarf standards, in preference

to espaliers.

Dwarf-standards occasion less trouble to keep them in order than espaliers, and are (generally) more productive; for Espalier trees are seldom managed well, and thus appear unfightly; at best they are stiff and formal, and obstruct the fight in viewing the quarters of a garden, which (if in order,) are worthy of coming under the eye: the violence done to nature, to keep espaliers in form, is commonly paid by pains and difappointment. A writer of repute observes, apples on French paradife stocks, planted at eight or nine feet distance, pruned and kept in an easy manner, make a fine appearance, and produce better fruit, and in greater quantities, than when they are in espaliers; Dutch paradife stocks however last longer, and are altogether superior. For managing Dwarf trees, see Pruning.

If Espaliers are planted, let them be only fruit of the best sorts, and in spacious gardens, where they may have a good length and height allowed them to grow freely; and let it be resolved to do the business neatly. If they may have nothing better than poles or stakes to be trained to, let them at least be strait, and of some equality in size, as to height and thickness, smooth, and not too clumsy for the purpose; fix them well in the ground, upright, and about nine inches asunder; at first only sour seet from the ground, and raised as the trees advance in height. Apples on paradise stacks best suit for espaliers in small gardens, and pears on quince stocks, as they maintain a small size; but they are apt to decay by the cutting they must have, and so

do not prove enduring trees.

Espalier

Espalier trees should rather be trained to sawed materials properly framed together, smoothed and painted. But for a year or two, they may be fastened to light stakes, when they will have formed a head, to begin to train them for bearing in the neat manner proposed; i. e. to slips of deal joined to light oak posts as trellises. Whether the slips be placed perpendicularly, or longitudinally, feem indifferent. If the longitudinal mode of training be the best approved, strong iron wire, may be recommended to run through the posts, instead of flips of wood, as it shades less and is stronger and neater. If upright slips are used, they should be slender, and from fix to eight inches diftance, according to the greater or less freedom of the natural growth of the tree. The height may be also according to the nature of the tree, from five to fix feet; and it will not answer to have them lower. Only a moderate length of trellis (on each hand) need be fixed at first, and so additions made as the tree extends. The posts may be about four feet afunder, the hrit on each hand, being two feet, or a yard, from the ftem of the tree.

Apples should be allowed twenty-four seet and pears thirty; except those graffed on paradise or quince stocks, for which little more than half this distance may do. Cherries and Plums should have about eighteen or twenty seet allowed them. Quinces, mediars, mulberries, and filberds may also be espaliered. The trees should be planted about a yard from the edge; but farther off were better, especially if the walks lie deep of gravel or poor materials.

The Breda, and Bruffels apricots, have succeeded in espaliers, as also in dwarf and full standards; but the general climate of the place must be mild, and the situation they are planted in must be very sunny and well sheltered: The fruit from standard apricots is very fine, and abundant; but they come not to bearing un-

der feveral (sometimes ten or twelve) years.

Currants,

Currants, goofeberries and rafpberries, do well espa-

liered, as to a production of early and fine fruit.

Trees of a more humble nature, and shrubs, next occupy attention in furnishing a garden. Currants and goofeberries (as bushes) should be planted three seet from the edge, and full six seet asunder. Some of these very useful shrubs should grow in every aspect of the garden, in order to have a succession of their fruits, as long as may be. Those who choose to plant whole quarters of currants and goofeberries, ought to do it at six seet asunder in the rows, and the rows eight feet from one another.

Raspherries may be set in plantations, in rows five feet afunder allowing three feet between the plants. Though these shrubs are best by themselves, yet here and there by the walks a detached bunch may be kept, Between or here and there one against a warm wall. rows of raspberries planted at the above distance, coleworts, early cabbages, cauliflowers, and lettuces may be fet, or spinach sowed in drills, the raspberries having had their pruning and dreffing early in Autumn, for the purpose. Every year a little short manure, dug in close about the roots, (and deeper as the plantation gets older) will insure fine fruit. Raspberries are not very nice as to foil and fituation; but the twice bearing fort should have a dry foil and warm birth to forward the crops, that the last may be in time: See that the plants to be fet have good brushy roots, and two or three eyes to each root near the stems, for the next year's bearing. The smooth wooded, or cane rasp, is rather to be preferred.

Strawberries may be planted at the edges of borders and quarters, either in fingle or double rows, (rather the latter) for the convenience of gathering, and for ornament; but the common and best way is, in four feet beds, with eighteen inch or two feet alleys, on which beds may be five rows of the wood and Alpine, four of the scarlet and pine-apple, three of the

he its

es g. be

ers er or

ur vs,

he ia, Carolina, and two of the Chili; fetting the plants at the same distance in the rows, as the rows are from one another in what is called the quincunx order. In a good, cool, loamy soil, which suits them best, a little more distance may be allowed the sour first sorts; and in quite a dry light soil, somewhat less, that they may shade one another the better from drought.

The best situation for strawberries is an open and sunny one, as thus they bear more, and finer slavoured fruit. Some of the scarlets should be planted under warm walls to come early. The woods bear shade as natural to them, and the alpines do tolerably well in it: As lengthening the season of fruit is a desirable circumstance; for these three sorts (at least) the situation

should be various.

The most proper time for planting the strawberry is the first moist weather in September, (or even earlier) that they may be established in the ground before winter, and they will bear the better the first year: Frost is apt to throw up late planted ones, and injures, if not destroys them. Those planted in spring often fuffer from drought, and bear very little the first year, except the alpines: Choose forward runners for planting, and let them be from beds in full bearing, i. e. of two or three years old; for plants from old beds are not fo fruitful: Take care also they come from beds producing fruit good in its kind, and true as to fort: Much depends on this, fee Nurfery. Press the mould to the roots, give them a watering, and again once or twice, if the weather proves dry. Some gardeners let them run over the beds, which in a dry, light foil, may be proper; but in this case, a greater distance should be allowed them at planting.

If the alpine fort be planted on a warm border, eighteen inches asunder, and suffered to spread, the first runners will fruit the same year, and sometimes

this prolific strawberry bears till November.

Fresh

Fresh plantations of strawberries should be made every fourth year, though in a good foil, and with good management they will continue longer; fo that where they are fuffered to run, the plants being frequently renewed, and old ones removed, beds have borne tolerably for ten years. Some gardeners infift that this fpreading mode is the best way of cultivating the straw-In a dry feason, such full covered beds have the advantage; but in a wet one, the fruit is apt to rot, though still in such a season, it is cleaner than from plants growing in an open way; but this carries the appearance of, (and rather argues) neglected culture. See the sections, nursery, pruning, and fruits. The method of keeping them in detached plants produces the largest and best ripened fruit, and on the whole is preferable; for this practice there cannot be a stronger argument, than that those follow it, who cultivate the strawberry for fale. See section 17.

The watering of strawberries should not be neglected, doing it almost daily, when in flower and are setting their fruit, if the weather proves dry, particularly to those under a warm wall; but this is not to be continued when the fruit is nearly ripe, which would

spoil the flavour, and dispose them to decay.

Flowering Shrubs may be dispersed about, and herbaceous perennial flowers; but plant them not too near the edge, lest they hang over the walks: The bulbous

forts may however be within fix inches.

Asparagus and artichokes should be thought of, but they take up much room, and in small gardens may therefore be left out. It will be of little use to have less than fifty or fixty feet of asparagus beds, as there would be so few heads to cut at a time; and artichokes must be planted wide, or they will not grow large and sleshy, in which their merit consists.

Let not pot herbs be forgot, but provide a general herbary in that part of the garden which is most con-

tiguous to the kitchen

١,

Having spoken of stationary things, the routine of the scassons must dictate the rest; and the inclinations of the palate will refresh the memory to take care of providing the most necessary and agreeable esculents for dressing, and raw sallads.

Perennial flowers have been mentioned; but let fancy direct as many annuals, and biennials to be cultivated, as room can conveniently be found for, that the garden

may be, as much as possible, ornamental.

In furnishing a garden with shrubs and flowers, respect should be had to their usual beight, their bulk, colour and season, (see section 19) that the mixture may be properly varied, harmonious to the eye, and come in regular succession. The latter end of the year is seldom provided for so well as it might be; late slowers should be set in warm situations, as their proper place. In the most dreary months, by judicious planting, evergreens in their neat and chearful "winter liveries," may be viewed from our windows, and serve instead of slowers.

Those who garden upon a large scale, should take care to have every thing proper and convenient as liberally provided. Let there be a well situated place for bot-beds, with some building as a tool bouse, and (if dry) for keeping bulbs, seeds, and berbs. Those also who garden even upon a small scale will do well to have every needful implement: It is the way to save time and labour, and have the work done well.

If water can be introduced, and kept clean with verdant banks around it, it would be found very useful where a garden is large: but let it be as near the center as possible, as the most convenient situation. It should be fed from a spring, and (if it could) be made drip into the reservoir, because its trickling noise is agreeable in a garden to most ears.

Mixed Gardening, as comprehending the useful with the sweet—the profitable with the pleasant, has been the subject hitherto; but if the flower garden and the

kitchen

kitchen garden are to be distinct things, the case is altered; not so much indeed, but that still the kitchen garden should be adorned with a sprinkling of the more ordinary decorations, to skirt the quarters, which should be chiefly those of the most powerful sweet scents, as roses, sweet-briars, and honey-suckles, wall-flowers, stocks, pinks, minionette, &c. in order to counteract the coarser effluvia of vegetables, or of dead leaves, which are too commonly suffered to annoy.

The flower garden (properly fo called) should be rather fmall than large; and if a separate portion of ground be appropriated for this, only the choicest gifts of Flora should be introduced, and no trouble spared to cultivate them in the best manner. The beds of this garden should be narrow, and consequently the walks numerous; and not more than one half, or two thirds the width of the beds, except one principal walk all round, which may be a little wider. The gravel (or whatever the walks are made of) should lie about four inches below the edge. The beds for tulips, hyacinths, anemonies, ranunculuses, &c. may be three and a half, or four feet wide, and those for fingle flowers the fame, or only two and a half feet wide in the borders; which was the most usual breadth in the old flower gardens. Let the beds lie rather rounded in the middle; but the walks flat.

Figured parterres in scrolls, flourishes, &c. have got out of fashion, as a taste for open and extensive gardening has prevailed; but when the beds are not too fanciful, but regular in their shapes, and chiefly at right angles, (after the Chinese manner) an assemblage of all sorts of flowers, in a fancy spot of about sixty seet square, is a delightful home source of pleasure, worthy of pursuit. There should be neat edgings of box to these beds, or rather of neat inch boards, to keep up the mould. Be sure to keep the box from the very first (as soon as rooted) and always after, as low as possible: Clip it twice a year, April and July.

f

An orchap may be spoken of here; i. e. a spot to plant standard fruit trees in, which are forbidden a place in the garden; but it must not be a small spot. The front row, should be balf standards, and before these may be a row of dwarfs; observing to plant the most towering forts (in kind) of the full standards behind. The ground should be dug thoroughly as low as the proper soil is, and if not naturally good, let it be improved by dung duly rotted, and worked well in a full fpade. In a strong foil lime should make a part of the manure. If the ground be naturally uneven, it will not be proper to level it, as this would rob the higher parts, and needlessly enrich the lower. A strong cool foil does best for an orchard, but it must not be wet. If it holds up water, it should be well drained

by trenches.

A piece of ground defigned for an orchard, would be greatly improved by first cultivating it as a kitchen garden for a year or two, manuring well at the time: Or, give it a good tillage; let it have a winter's frost, by deep trenching into high ridges, turned over in fpring, and fummer fallowed. The trees being planted, at proper distances, the ground may be kept under some fort of crop, for several years to come, with proper dreffing. In a large orchard, the plough may be used for corn, potatoes, &c. If the soil is poor, every opportunity should be taken to give it a little manure, that there may be proper food prepared for the roots, as they extend. No doubt many orchards would bear much better, if the whole ground (as the roots extend far) were before winter dug or ploughed over every fecond, or third year, and dreffed, by digging in some rotten dung, or sprinkling over the whole (when rough dug) foot and pigeon's dung, or that of " any other poultry; this will wash in by rains and inows, and do much good. Or if an orchard were ploughed,

di

of

pa

ca

tr

CO

01

g

110

fe

b

0

it

ploughed, or rough dug, every year, immediately after the fall of the leaf without manuring, it would be very beneficial; for it is not adviseable to give trees

much dung.

The thinning of the branches of orchard trees, by an occasional use of the saw, bill, chizzel, or knise, should not be neglected, that the air, may have free course, and the sun access among the branches: This is more especially necessary in thick planted orchards, and the benefit of proper pruning is very great, though much neglected. See Pruning of Standards, Section XII.

To succeed well, apples and pears should be planted from thirty to forty feet asunder, and cherries and plums from twenty to thirty, according to the richness of the land. The walnut should be rather planted singly; but if in a number together, ought to be forty feet asunder for fruit, and thirty for timber. See Nursery. These distances appear great, but it is necessary, as after a few years closer planting would be found evident. See planting and pruning, Sect. 9, 12.

If the intermediate ground is not cultivated, as before recommended, some fort of fruit (as cherry, plum, or codling) or young forest trees may be planted, to be removed in time; or currants, gooseberries, &c. it may be kept also in grass, the trees thorned, and small cattle turned in; which grass, as it comes early, will be found particularly useful to those who have much stock. On this subject, it may not be amiss to give the instructions

of one of our best gardeners.

It is an error (says he) to let turf cover the surface of the ground in an orchard. The trees should be at such distances, that a plough may go between them, and in that case the trees thrive every way better; the breaking of the ground serves as manure without its rankness, and the sun and air have free passage, which is very essential to the good taste and well ripening of the fruit. Where the plough cannot be used,

dig the ground a full spade deep, picking out the roots of weeds.

The best manure for an orchard, is a mixture of two parts dung and one part coal-soot. Let this be blended carefully, and spread all over the ground, between the trees, not piled up in heaps just about their stems, according to the old practice.

The cultivation of the ground about the trees in an orchard, is more neglected than any other part of the gardener's business, yet there is not any thing more

necessary. Hill.

## SECTION IV.

### OF THE CULTIVATION OF A GARDEN.

THE cultivation of a garden includes the doing all those things that are necessary, in order to a sea-sonable and prolific production of the various vegetables, fruits and flowers, we are disposed to propagate.

The foil must be first attended to, always to keep the fruit borders in heart, and the quarters in a proper state for use, when called upon to receive either seeds or plants. Ground should never lie long without stirring; and if all is so well as might be, or not, it must be borne with; but the soil of a garden, should have a free, sweet, and rich soil, by proper digging, &c. or no great things can be done, as to forward, hand-some,

W

fome, or well flavoured productions. It should be free, that the roots of plants may not be impeded in the quest of food; fweet that the food may be wholesome, and rich that there may be no defect of nutriment.

Trenching the vacant ground in a garden, does good to all foils in the autumn and winter seasons, and that in proportion to its strength, being indispensibly necessary for clays to separate the parts: The light soils may do by being only rough dug, which is a method that stronger soils may be also benefited by. The soil would be still farther improved, by re-trenching, or rough-digging, once or twice in the winter, if the opportunity offers, particularly if strong or stubborn Let the ridges lie E. and W. except the ground be solope, when they may be in the direction that does.

When manure is applied, the ground is not to be glutted with dung; for a little at a time, well-rotted is sufficient, so that it comes often enough, as opportunity, and the nature of the cropping may dictate. It is indeed a fort of rule with gardeners, that ground should be dunged every second year; but circumstances may make more or less of it necessary, and rules should never be indiscriminately applied. If dung is pretty well reduced, (as it were to earth) much less will do, and let it not be buried too deep; but if it is otherwise, lay it low, to be dug upwards another time, when it is more consumed.

It is an excellent way of manuring, especially where the superficial soil is much exhausted, to spread over rotten dung, late in autumn, in the winter, or early in spring, and so let it remain, till the ground is wanted, before it is dug in; which should however be slightly dug before the manure is put on, or forked in a little afterwards. This method is particularly to be recommended where crops of onions, leeks, and such superficial rooting plants are to be.

Dung used in great quantities, and lying in lumps, breeds worms, grubs, and insects, and makes plants

d by grow too rampant and rank flavoured. Carrots it cankers, and it disagrees with many things; it is apt also to make the ground parch, and burn the crops fown upon it in a hot fummer. On these accounts some persons have been induced to dress their gardens only with rich fresh earth; which, if they do not overcrop, will do very well, being accompanied with good tillage; which alone is of much use and is effential to due cultivation. Vegetables are always sweeter, the less dung is used, and little need be used, when the natural foil is good and deep; for the earth may be fo dug, that what is at the top one year may be at the bottom the next: which is a manœuvre evidently advantageous, as a good part of the strength of the top foil washes downwards: The method just recommended, of letting dung lie on the furface for a time, is good alfo, as it abates the rankness of it.

If the ground is in proper heart, every fpot may be contrived to be constantly and successfully cropped. The common gardeners about London, and other great towns, who give high rents for their land, contrive (manuring well) a succession of crops, one under another very dexteroully; and this fort of conduct should be imitated by private persons. Thus a little spot, in skilful and industrious hands, shall be much more productive than a much greater under contrary management: But when hard worked, the foil will not do

without a good deal of dung.

A caution must be observed, for if plants grow crowding thick, it defeats the end in view; and fruit borders must not be much cropped, furnishing them chiefly with small plants, of short duration, and superficial growth, left the roots of the trees be too much robbed and shaded.

Have an eye on vacant ground, either for imme-

diate use, or to prepare it for future.

In the occupation of ground, the change of crops will be proper, as each fort of plant draws a fomewhat

roc

are

different nourishment: so that after a sull crop of on thing, one of another kind may often be immediated fown; but it should be contrived that a wide crop may follow a close one, and contrariwise.

Close crops, as onions, leeks, carrots, &c. are conveniently and neatly cultivated in beds of from four to five feet widths, with alleys of a foot to eighteen inches

between them.

The feasons proper for furnishing the ground with every particular vegetable, should be well attended to that each may be obtained as early as its nature will permit; and of the feeds and plants we use, can must be taken to procure the best of the kind, less after all the trouble of cultivation, disappointment a

to quality should ensue.

The quantity sown and planted is (in a degree) to be determined by the portion of ground that can be spared, but it should be always a rule, to sow and plant more than probably enough, as more may happen to be wanted than expected, and a cross season or other accident, may occasion a failure. As exact rules cannot be laid down, the exercise of a little judgment will be necessary, in order to proportion crops aright; for to have too much of one thing, and too little of another, is disagreeable. Respect should be paid to the natural duration of crops, some going off soon, and other being lasting, and that too according to the season they are propagated in. See, Of propagation, in the next section.

Seeds and plants should be adapted as much as polifible to the soil and situation which best suits them; for in the same garden some difference will be found, not only as to sun and shelter, but the earth; as some will be richer, some poorer, some deeper, some shallower, and some (perhaps) theavier, some lighter, in due attention to which, advantage is to be reaped.

Let the ground on all occasions be well dug.

Weeding in time is a material thing in culture, and firring the ground about plants, as also earthing up, where necessary, must be attended to; and in some cases pressing the mould to the stems of vegetables will be proper, for their better support. Earthing up well before winter frost sets in preserves plants, forwards, and improves them. Weeds exhauft the strength of the ground, and if they are suffered to seed and fow themselves, may be truly called, " garden ons:" The band and bee are the instruments for the purpose; and where the trouble is not too much, the former will generally be the best, when it is not thought necessary to fir the ground; which indeed may be done afterwards, when all is clean, to better purpose. Digging, where the spade can go, between the rows of plants is a good method of destroying weeds, and as it cuts off the straggling fibres of roots, they strike afresh, in numerous new shoots, to the great benefit of the plants. Deep hoeing gives a degree of fertility to the earth. Breaking the furface will keep the foil in health; for when it lies in a hard or bound state, enriching showers run off, and the salubrious air cannot enter.

The thinning of feedling crops should be done in time, before the young plants have drawn one another up too much. All plants grow stronger, and ripen their juices better, when the air circulates freely round them, and the sun is not prevented from an immediate influence; an attention to which should be paid from the first appearance of plants breaking ground.

In thinning close crops, as onions, carrots, turnips, &c. be fure that they are not left too near, for instead of reaping a greater produce, there would assuredly be a less. When they stand too close, they will make tall and large tops, but are prevented swelling in their roots: better to err on the wide side, for though there

are fewer plants they will be finer.

In the pricking and planting out of crops, be sure to do it as early as may be; let every thing be regular, (not sparing the line) allowing always room enough for this work; and being thus treated, vegetables will come forwarder, larger, and of a superior slavour. These advantages are seen in all things, but in lettuces particularly, which often have not half the room allowed them they should. Over cropping robs the ground of strength to no purpose, except increasing the dunghill; it makes it also inconvenient to weed, rake and clean up, which in a private garden (at least) it is proper frequently to do.

Dibble planting, as being easy and expeditious, is the common way of setting out plants by; but (except indeed quite small ones) they are best put in by a small spade or trowel. In the former method, the roots are frequently doubled and distorted, so as to receive (at least) a great check, if not to occasion a failure, when so put out towards winter; but in the latter way, the roots lie free and easy, and presently establish themselves in health and strength. There is more in this than gardeners in general allow of. Ground designed to be planted, is best dug a day or two before wanted.

Watering is a thing of some importance in cultivation, though not so much as many make it. It is a moot point, whether more harm than good is not on the whole, done by it, when it is thought generally necessary in a dry season. In a large garden, it is an Herculean labour to water every thing, and so the temptation generally prevails either wholly to neglect it, or to do it irregularly or desectively. To water nothing is too much on the dry side: but there is such a thing as watering too much, which spoils the slavour, and makes esculents less wholesome.

But watering will affuredly benefit some things; as (sparingly) new planted trees, slowers and vegetables. Watering is of use to settle the earth about the roots of plants newly set, for it is by a close union, (as it

as it

ere

were) of the earth with them, that they prosper. The watering of new planted things may be to be repeated, but it should not be done very often, as it is then apt to ficken, and rot the young roots. As foon as they are believed to have got hold of the ground, defift from When any plant is towards flowering then watering. moisture is more necessary.

Shading of new planted things, particularly flowers, is of much benefit, and that in proportion as the feafon is funny. So that the imitating a cloud by a shade, is evidently proper, and frequently necessary to the life of the plant, as neglecting this business has frequently proved: a little water in a cloudy time does

much good.

Strawberries and Cauliflowers are generally watered in a dry feason; that is, the strawberries, when in bloom, in order to fet the fruit, and the cauliflowers, when they shew fruit, in order to swell the head: In a light foil this ought particularly to be done. In very dry weather, asparagus seedlings, early turnips, carrots, radishes, and small-sallads will need watering. Slips, cuttings, and layers of any kind will need water. Pots of flowers must have it frequently.

When watering is undertook, let it be a complete business; i. e. to the bottom and extent of the roots, as much as may be. The wetting only of the furface of the ground is of little use, and of some certain harm, as it binds and cracks the ground, and so excludes the benefit of showers, dews, air and sun, from entering the foil, and benefitting the roots as they otherwise would do. Wetting the surface of the ground, (however) in a fummer's evening, as it makes a cool atmosphere, a dew is formed, which pervades the leaves,

and helps to fill their exhaulted vellels.

Watering the roots of wall-trees, (if dry weather) when the fruit is fetting, is by some thought necessary. The best way to do this effectually, is to make a few holes at some distance from the tree with a smooth iharp

f

ł

b

S

i

r

C

b

f

le

ar

W

fe

of

m

pa

di

fec

10

the pointed stake, the better to let the water down; but this may wound the roots, and should only be practiced in a light soil, and very dry season. To young trees only it can however be of use, for the roots of old ones run far and wide; and it is the small sibres of these distant roots, on which the tree chiefly depends for food. Vines should have no water till they are off blossom, (July) and the fruit as big as large pin's heads; and then if the season be very hot and dry, watering the roots twice a week will help the fruit to swell.

An engine to water the leaves of vines, and all other wall trees in a summer evening, refreshes them much, and helps to rid the trees and wall of infects and filth. Late in the summer, when the nights begin to get cold, it is time to leave off all watering, except things in pats and frames, which should have it then only in the morning. As watering is apt to make ground hide-bound and unsightly, let the surface be occasionally stirred and raked, which will make future waterings enter the ground the better: when the ground is hard on the top, the water runs away from its proper place, and half the labour is lost. Many things are impatient of being kept wet about the shanks, and therefore watering should be generally at a little distance.

The quality of water used for refreshing plants is a material thing, and it is very various in its nature, according to the peculiar earths and mineral substances, that it passes through. Rain water is by far the best, as appears by the verdure and vivacity it gives: It is

nourishing, as being full of vegetable food.

River water is next in fitness, and pond water follows, if it is sweet. Well water is of least account, the local circumstances occasion its use the most. So that in forming a judgment concerning watering, it is not simply to be considered, whether plants should be watered; but whether with well water, and that too from a pump. Pump water, if used directly (to say nothing of it's hardness) is so cold in summer, that the roots

feel an extreme fensation; for as they are then warm, through a lively fermentation in the earth, great cold fo contracts their veffels, that they perform their proper

offices with difficulty, and become difeated.

Hard water is fostened by throwing in a little dung, lime, marle, or earth, and rather that of a loamy nature, or clay, which will greatly fit it for use. Some persons keep chalk in wells, cifterns, &c. to foften the water; and others have kept hard water on bruifed offer-shells a few days in a tub, with a view to watering flowers, &c. others have put a bag of barley in it, finding the water that has been used in malting, is rendered very folt, though ever to hard when put on the grain. Fresh bran fostens water much, stirring it up now and then for a day or two. At any rate, however, let hard water stand exposed to the fun and air, as long as may be; a few hours will improve it, but a few days will better qualify it for vegetation.

Water is fometimes, enriched with dungs and falts. Some experiments of putting a small quantity of nitre into water to keep flowers flourishing in phials, and rooted plants in pots, appear to prove beneficial. courfer way of impregnating water with dungs may be useful to pots of plants that are too full of roots, or to any thing growing in a poor foil; but the water should not be made too rank, or suffered to touch the leaves; it should stand also in the sun two or three days, and be stirred up now and then. Sheep's-dung is that which has been used for the purpose, and is to be preferred, though others may do. Let the rule be, to impregnate the water about an equivalent of an ounce of fea-falt to a gallon: A stronger mixture might do mischief; yet a rich one poured plentifully on old afparagus beds in autumn and spring would do much good.

The MANAGEMENT of a garden, as somewhat distinct from the cultivation of it, is an object of consequence; i. e. to keep it in such ORDER, that it may not offend the eye, or fail in those general impressions

D 3.

of pleasure it is capable of affording, when things are shewn in their best manner. A garden may be cultivated so as to be prositable; and yet not conducted so as to be agreeable to walk in, which in a private garden is a circumstance surely to be lamented: The proper appearance of a well managed one is expressed by the word NEAT: Let all be done that can be in order to it.

To be neat, weeding must be industriously followed up, and all litter that is made in working, quickly carried off. The ground also should be frequently stirred and raked between crops, and about the borders, to give all a fresh appearance. There is a pleasantness to the eye in new broken earth: and when there are no flowers left in the borders, this gives an air of culture, and is always agreeable: The observation is particularly meant to apply in autumn, that the garden may not become dreary too foon, and fo bring on winter before its time. An Asparagus fork is expeditious and useful in this case; but it must be slightly used, lest it diffurb the roots of plants too much. Vegetables should not be fuffered to rock themselves by wind, so as to form holes round their stems, but be well earthed up (49) or otherwise supported.

Trees and shrubs should be constantly freed from suckers and dangling shoots, and wall trees ought to be regularly kept in order agreeable to directions in the

fection, On pruning.

Let gravel walks be kept free from weeds and moss, often swept, and weil rolled after rain. If there is quantity of gravel enough in the walks to relay, or turn them up every spring, or once in two years, it will thoroughly clean them, and make them appear lively. Moss may be either scraped off with a trowel, or some such instrument, or rubbed off by repeated strokes of a broom not quite new.

Grass plats and walks should have their edges occafionally cut, and be mowed, as often as there is the least hold for the scythe, for they lose much of their

beauty,

ar

ed

a-

16

ir

beauty, when the grass gets long; leaves should not be suffered to remain on them as it stains the grass;

and worm casts should be cleared away.

Edgings of all forts should be kept in good order, as having a fingular neat effect in the appearance of a garden. The dead edgings will sometimes, and the live edgings often want putting to rights; either cutting, clipping, or making up complete. Where there are no edgings, or but weak ones, let the earth bordering on the walks be kept firm, and now and then worked up by a line in moist weather, beating it smooth

with the fpade.

Some fruits may need support, by tying their weak branches when they get heavy, to stakes, &c. Rows of raspherries and beans are kept neatly up in their lines, by putting in here and there a stake, and using packthread lengthwise; and thus will they bear better, and be more conviently gathered. Strawberries of fine heavy sorts, will be preserved from getting dirty and rotten, by tying their stems to little sticks; by this practice the fruit also gets better ripened, and of a finer slavour: Some persons lay tiles, or moss round the plants, when the fruit is half grown; but this is not (generally) so well, only it has the advantage in keeping the ground cooler in a hot season. The first and finest scarlets best deserve this trouble.

Flowers should be frequently seen to, to tie up, and trim off dead and dangling parts. Some of them cannot do without support, and many forts are made more secure and beautiful by proper ties. If this business is neglected, a heavy rain, or strong wind may come, and lay all prostrate, especially about the equinostial seasons; but weakness, or their own weight, will often

bring flowers down.

The *flicks* used for flowers, should be of smooth wood, as hazle or fallow, or of neat painted slips of deal, with or without an ornamental head; white is the best colour, on account of its contrast with the leaves.

D 4 New

New bass werted, fine soft packthread, or green yarn are proper for the ties, which should be twisted first round the stick, and then round the slower: let the ends of the string be cut off close. The sticks should have smooth and sharp points, otherwise they may damage the roots, and will not hold so saft in the ground; thrust them in as far from the stem as conveniently may be, and let attention be paid to bulbous roots not to go so near as to wound them. Do not think of forcing all the branches of a large bushy head to a single stick; but let two or more be used, as may appear necessary, observing that there is something of an equality of size in the sticks used to the same slower.

Some persons are very incurious about their flower sticks, which may rather be called stakes, even when applied to the smaller fort of plants. Sticks may also be too weak for large ones, and a due proportion is there-

fore necessary to propriety and neatness:

Decaying flowers should be timely trimmed or removed, and perennials should be regularly freed from the parts running to feed, (except so much as may be wanted) as the production of seeds weakens the root much; sometimes even causing death, and thus many curious perennials have been lost, especially the first year of planting them. To preserve any particular sort therefore, let the stems be cut down as soon as the slowers appear to be going off, or to secure the root in strength, let them not slower at all the first year.

Vegetables decaying are offensive, and those prematurely spindling, and superstuous ones, sprouts, &c. running for seed, should not be suffered to continue in the ground (as they often are) to exhaust its strength,

and look unfightly.

The management of a garden (summarily speaking) confists in attention and application; the first should be of that wary and provident kind, as not only to do well in the present, but for the future; and the latter should be of so diligent nature as (willingly) " Never

to defer that till tomorrow which may be done to day:"
—Procrastination is of serious consequence in gardening; and neglect of times and seasons is sruitful of disappointment and complaint. It will often happen, indeed, that a gardener cannot do what he would; but if he does not what he can, he will be most justly blamed, and perhaps censured by none more than HIMSELE.

# SECTION V.

### OF PROPAGATION.

PLANTS are propagated by feeds, fuckers, flips, offfets, divisions, cuttings, layers, and graffs.

By feed is the most general method of propagation, and plants raised any other way are seldom so fine. Those plants from seed which have never been removed, are commonly handsomer, and come forwarder, than those that have been transplanted, provided they were sown in a proper soil and situation.

As upon feed being right in kind and good in nature, depends the defired fuccess, care should be taken to procure the best, and no temptation suffered to prevail for the use of an inferior kind, or of one only suspected of being so, if it can be helped; for to cultivate a soil, and use a wrong or desective seed knowingly, is folly indeed!

The largest seed of the kind, plump and sound; is to be chosen being well ripened and kept from niuries.

of weather and infects: for, as the largest animals produce the most profitable stock, so it is in vegetables; which directs the gardener always to save seed only from the forwardest and handsomest uninjured plants. As in animals the young may be stunted by bad management, and desective sood, so in vegetables, the seed being good will not be alone sufficient, if the soil

and culture be not right.

Commonly speaking new seed is to be preferred to old, as growing the more luxuriantly, and coming up the surer and quicker. This circumstance induces some private persons to save their own seed (a practice not however altogether to be recommended) that they may not be deceived in buying old for new seed; a trick of trade, it is to be hoped, not practised by every seedsman: Yet a little mixture of gld seed is sometimes proper, because the new is perhaps cut off, and the old saved, by being a day or two later in coming up.

If old feed is knowingly fown, some allowance in point of time must be made. Peas and beans of two years old, are by some preferred to new, as not running so much to straw. See cucumters and melons, section 14.

As to the age of feeds, at which they may be sown and germinate, it is uncertain, and depends very much how they are preserved. Seeds kept from the air and moisture by being buried deep in the ground will continue a great many years without corruption. Peas and beans will germinate very well at seven years of age; but the seeds of lettuces and kidney beans, and some others, are not to be depended upon after a year or two; and though generally speaking the smaller seeds are of the least duration, yet their maintenance of vegetative power depends much upon the texture of the seed, with respect to its coat, and the oil it contains, &c.

The faving feed is hardly to be recommended. Things running to feed give a garden a rude appearance, often occupying ground that is wanted, and might be used to better purpose; and the case often is,

that

that feeding plants (in private gardens) are neglected in fome measure, or destroyed by birds, and come to little at last. Perhaps they are not saved from proper plants. It is a particular business to raise seeds for sale, and (generally) they are best had from those whose

province it is to deal in them.

Against our own seed, there is this to be observed, that it is a received maxim to procure feeds of esculents from a different foil and fituation, or at least to change them, as being apt to alter or degenerate, if repeatedly fown in the same place. It is proper, however, for private persons to save seed sometimes, in order to fecure that of any particular fort, that it is judged may not be got fo true and good. Yet here perhaps the buly bee or wind may interfere, and disappoint expectation; for if there is any thing of the like kind in a neighbouring garden, these instruments may carry the Farina of that to our charge, and contaminate it, fo as to produce a fpurious offspring, which is very frequently experienced in the cabbage tribe. Now this cannot in a great degree happen with those who raise feed in extensive pieces of ground occupied with the fame fort of vegetable.

Seed of vegetables should be saved from fine forward plants, secured from rocking about, when they get tall; guard them against birds, gather them regularly as they ripen, lest they shed and are lost, and keep them dry. Flowers, it may be proper to save the seed of, and it is little trouble. The forts may thus be better depended on, and the small quantity wanted of each kind makes it hardly worth while to buy, if we can raise them ourselves, or get them of a friend; no single flowers should be suffered to grow in a garden where there are double ones to bear seed, as larkspurs, and holybacks, for the Farina of the singles transported by bee or wind will spoil the seed of the doubles. Such single flowers should be taken up as soon as ever discovered to be so. It should be a rule for flower seeds

f

in general to be fresh from year to year; though if kept dry, and from much air, many sorts will grow that are older: cursons flower seeds are kept well in vials: others may be in small draws, and some kept on

thelves in their pods.

Seeds may be forwarded for fowing by various ways of procuring a germination before they are put into the ground. In fummer it has not been unufual to fleep both broad and kidney beans in fost water, or milk and water, about twenty-four hours, to forward their growth, and to afcertain their vitality. If the ground is very dry when these seeds are committed to it, either steeped, or not, it is a good way to make drills or trenches to plant them in, watering them well first, and then pressing the seed in a little. Any fort of the broad beans, or even peas, may be forwarded, when ground is not for the prefent ready, by laying them in damp mould, in a garden pot, or otherwise, a layer of earth, and a layer of feeds, &c. and they may be put into trenches (with care) when the radicle has got some length, the mould being light, and the work finished by a gentle watering.

The smaller seeds, as carrots, &c. may be prepared for sowing, by simply mixing them in a little moist fand, or fine earth, taking care that they do not lie longer than the usual time of their beginning to sprout: but this practice need only be adopted for feeds that are long in coming up, and then there is some advantage in having them to sow in a state ready to strike

immediately, on fresh dug earth.

The feason for committing feeds to the ground, should be as early as the nature of the plant to be cultivated will bear; for the forward productions, which come without forcing, are the best as to size and fruitfulness, if they meet with no material check from weather. It is the proper ambition of gardeners also, to have some of the first of each kind of vegetables and fruits, and thus to vie with others.

Let this direction for early fowing be understood, not only of spring, but autumn crops; that the plants defigned for winter use, or to stand for spring, may be strong, and well established in the ground: Though for those designed for spring, it is advisable to have two or three different sowings; for lettuces (as an instance) that are forward, will sometimes fail when

backward plants shall do well.

To be fure of a crop, and in some things a succession of crops, various fowings should be made through the year, at all times that are not too unnatural as to feafon; for it is an object in gardening, not only to have early and late productions, but never to be without what may be produced. Every fowing that is made (the early ones in particular) should be noticed. in time, whether it is likely to fucceed, that the work may be repeated. But a little caution is necessary, that this business be not over done; for though there may feem to be a sufficient distance of time in sowing for succession crops; yet they tread sometimes upon the heels of one another to fast as to occasion a disagreeable superfluity: This is often the case in peas and beans, in the height of fummer, and especially if a hot featon: this caution is the more necessary, where there is no ground to spare, or but few hands to culuvate it.

Sowings should be generally performed on fresholug, or stirred ground. The digging should therefore be done as near the time designed to sow as can be. There is a natricious moisture in fresh turned up soil, that softens the seed to swell and germinate quickly, and nourishes it with proper aliment to proceed in its growth with vigour, but which is evaporated soon after from the surface. If the ground, indeed, turns up raw, or wet (as early in the spring it is apt to do) a little time must be allowed it to dry, and so also if rain salls first. In this case, seed should be sown as soon as ever the ground may be trampled on not to bang to the

the feet, for when the foil is too wet, it binds and does harm, especially heavy ground; thus in this work, and every other in the way of gardening, there is a nicety of time to be observed, by those who would do their business well. It is to be observed, however, that sowing in drills, or on beds that are not to be trampled, the moisture of the ground is rather an advantage, provided, in the last case, that the ground will admit a rake, and the soil is not too wet to drop somewhat loosely about the seeds.

The proper depth at which feed should be sown, is to be carefully observed: if too deep, they will either rot, or not vegetate, or thrive well; and if too shallow, they are liable to be injuriously affected by frost, wind, drought, or birds; but of the two, rather too shallow, than too deep, is best, and this we are taught by

nature, whose sowings are mostly superficial.

The smaller the seed, the finer should the soil be, and the less also the covering; so that, while some, (as the seed of celery is to be but barely covered, others as peas and beans) may have a depth of two, three, or four inches. But some regard is to be had to the season and soil:—in a warm season, and light soil, sow deeper,

and the contrary shallower.

The quantity of seed sown, is a thing to be attended to with some exactness. Small seeds go a great way, and require a careful hand to distribute them; for though sowing a little too much be a trisle as to the value of seeds, yet to have them come up crowding thick is an evil. To sow evenly as to quantity, is an object of practice worthy of care, as it secures a better crop, and more easily managed in the thinning. If the seed is suspected, sow thicker; poor land will require more seed than rich.

It is not generally advisable to sow several forts of seed on the same spot, as some persons are accustomed to do. The gardeners about London sollow the practice; as profit is their great object, and not neatness or propriety.

priety. On the same piece, they sow radishes, lettuces, and carrots; the radifhes are drawn young for the table, the lettuces to plant out, and a sufficient crop of carrots is left, for carrots should not be very near to grow big: this is as reasonable a combination as any that is made; but still, if not short of ground, each kind separate will be found best. In defence of this mode of culture, it is faid, if one crop fails, the others may do, and there is no loss of ground or time; and if all succeed they do very well. Radishes and spinach are commonly sown together by the common gardeners, and many manœuvres of inter-cropping are made by them, as fowing, or planting, between rows of vegetables that are wide afunder, or prefently to come off, or in the alleys of things cultivated on beds. But this crowding mode of gardening will not be imitated by private families, except there is a want of room to bring in a proper fuccession of crops. Some little things of this fort, however, may well be done; as, a piece of ground new planted with horse-radish may be top-cropped with radishes or spinach, &c. A thin crop of onions upon new asparagus beds, may also take place, drawing them while young from about the plants.

The proper covering for seeds at broad cast being determined on, as to depth, let the ground lay the rougher, the deeper the seed is to be buried; and if it is to be scarcely covered, rake the ground first very level and fine. All seeds come up best when moderately pressed with the earth; for if they lie too lightly in contact with it, cold and drought more easily affect them, and when once seeds begin to germinate, they are impatient of both. To trample seeds in is on the whole better than any other pressure. According to the depth it is intended to cover seeds, the seet should be set wider or nearer, i. e. the closer for the less covering. Begin to trample on the outside, walking regularly, lightly, and steadily round the piece, till the middle be arrived at in the finish. This done, lay all

immediately and neatly level with a wide rake, drawing off stones, &c. but do it lightly, to avoid driving in the teeth of the rake, which would remove the feed,

and make it come up irregularly.

Patches, or small pieces, are sometimes sown without trampling, particularly of flowers, by drawing some of the mould on one side, and then sowing and covering the proper depth with what earth was drawn off, adding a little more, if necessary. In this case, if the soil is not heavy and wet, press the surface with the rake head, spade, or otherwise. Seeds sown in drills, or rows, are seldom pressed, but they should be, especially if the soil be light; and even beans set by a dibble, are best to have the earth pressed about them with it, or afterwards with the rake head, and they will support themselves more erectly, for the least wind rocks them about when in loose holes: In a light soil, the best way is to lay them in a trench, and trample farmly in.

Directions for thinning feedling crops, and pricking them out in time, were given in the last fection. Let this business be done properly, and prick out enow, that there may be some to spare; perhaps a neighbour may be obliged thereby, and at any rate it is best to

bave plenty, lest accidents happen.

Propagation by fuckers is a mode of culture rather peculiar to trees and shrubs. The things to be observed in this business are, to take them up with some care from the mother plant, so as not to injure its root, nor the sucker's own root, by pulling it up without properly loosening it first. The earth should be moved aside by a trowel, and then the sucker cut off by a single, and not with a spade, as is common. Of those hardy things that there is plenty of, this rough way does not signify much, as to the sucker; but it may injure the root too much that it comes from. Wherever a root appears barked, the part below should be cut off. If it is desired to succeed well, in propagating

by.

by fuckers, confider that all young roots are tender, let them be trimmed to form, and planted immediately, or at least let them be covered with earth or laid by the heels, as it is called. Suckers with poor roots,

must have their heads reduced accordingly.

Propagation by flips is of two forts, either from the root, or flem; and feveral forts of flowers and herbs are increased this way. When from the roots (if the whole is not taken up) move the earth carefully aside, and slip off by a pressure of the thumb and singer, and be cautious of hurting the sibres of the slips, planting with sme and good mould about them. Take off slips from the stem carefully by a push of the thumb, and not too many from the same plant, as it is apt to injure the place a little by tearing off some of the wood. Slips from the stem are to be considered as cuttings, and treated accordingly. They take more certainly, and make better roots than cutting; but are apt to injure the part from whence they are taken.

Offset is a term sometimes applied to slips from six brous roots; but more properly so from bulbous roots, which put forth many offsets. These are slipped away at the time they are taken up for removal or replanting, and commonly take two or three years before they bear slowers: dispose of them therefore in a nurfery, where they may remain undisturbed while they

come to a flowering state.

Division of the roots is a way of propagating many forts of plants. To this end (of course) they must be taken up, and then either carefully pulled, or cut asunder with a sharp instrument; as the case may require. It is not safe, however, to divide such roots into very small pieces, (especially if cut), as then they are apt to die; but leave them of a size sufficient, not barely to secure life, but to form immediately a handsome head. The general season for thus splitting sibrous rooted plants, is October, but it may be done early in the spring.

Cuttings of a variety of woody plants will grow, and many trees and shrubs are propagated this way; but their sap must be of a watery nature, as those plants that are gummy will not strike, (or ravely) though ever so much care is bestowed, or time allowed them. The texture of the wood of cuttings must be somewhat soft, as hard wooded ones will not grow. Cuttings should be rather short than long, and kept steady in the ground. If they are planted where there is any likelihood of their being disturbed, they may be tied to a stick, well saftened in the earth.

The feason for setting slips and cuttings is for some things summer, as wall-flowers and myrtles; and for most, from October to March, but (in general) the sooner the better. It has however been said, that spring is the best time for all, and that the sap should be in motion first. This is at least true of some things, as cuttings of the vitex, or chaste tree, (though hardy) are found to do best in spring; and all cuttings from

plants of a delicate nature do fo.

Cuttings should be of well ripened wood, and have the earth pressed to them, the whole length that they are in the ground; i. e. from sour to six inches. Cut them with a sharp knife slopewise, and plant in a good soil, and in a situation where they only have the morning sun; and keep them cool (not wet) by occasional

watering in dry weather.

Laying of branches is a mode of propagation, that may be adopted for almost all forest trees, and several sorts of fruit trees and shrubs; i. e. all that will grow from cuttings, and many that will not. Layers are less rampant, and more fruitful than suckers; and "those who are curious, and find a seminal variety of any tree, or shrub, that is remarkably different from the original, the only way to have it preserved genuine is to convert it into a stool, (by cutting down) and raising plants by layers." They are made of the lower branches of the plant, and must be young and pliable,

o bend down without breaking, to the depth of four, ive or fix inches in the ground, (as the foil is light or heavy) at which they must be held securely by good begs; and if they cannot be brought down sufficiently

leep, some earth may be raised up to them.

Let the ground about layers be kept cool by occaional waterings, and laying some moss, turf, litter, or rather small pebbles about them, which will not harbour nsects. The part out of ground may be supported erectly by a tie to a stick. It is a good way to stit (with a sharp knife) the part at the peg, as in carnation layers, a little more than an inch; and some prick a few holes about the part (at a joint) with a blunt awl, to help the layer to strike root. For the hard woods, some gardeners make several slits, or chips, in the part layered in the earth, and bind the layer rather tight, just above it, with pliant wire; and foft wooded layers are fometimes twisted to crack the bark, in order to help the part to strike quickly. Generally layers should be shortened to fix or eight inches above the ground, but some gardeners chuse to do it to two eyes, that the produced shoot, or shoots, may be stronger.

Where there are no branches low enough to be brought into the ground, (and it is not thought good to head down for the production of low shoots, or fuckers) plants may be layered by fixing a broken pot, or a box, with a flit in the fide, to the height necessary to lay in a branch. A branch also, if long enough, may be thrust through the hole of a garden pot upwards, then filled with earth, and supported by some contrivance, and shaded by some means, and in both cases water frequently. Take care not to injure the buds in drawing through the hole of the pot. By this contrivance rooted plants being procured in pots, may be turned out with the earth about their roots undifturbed. A branch of a vine thus layered in November, may be next year cut off, when the fruit is ripe, brought

in the pot to table, and afterwards planted out.

The feason for layers is (generally) the same as sor cuttings, and some forts will be well rooted in a year, but others will require two, and sometimes three years before they will be fit to be moved. Those, however, that are flow to strike should be layered as soon as ever young thoots are forward enough, which may be in fully or August. This practice is particularly recommended for the phyllerea and alaternus. Cut off the leaves of the part that goes into the ground, because such young wood will not well bear stripping. For propagation of fruit trees by graffing, see the two next sections.

### SECTION VI.

#### OF A NURSERY.

THERE are so many nursery-men ready to supply our wants, that the necessity of a nursery is in a great measure done away; it affords, however, employment, amusement, and an opportunity for exercising ingenuity, and that particularly in the way of graffing.

By means of a nursery, trees are ready upon the spot, to be transplanted without damage to the roots from being long out of the ground, and the climate and soil being the sume in which they are raised and are to grow,

r. v.

s for

year,

hree

low-

foon

W,

grow, and to fruit, there is a fort of certainty of fuccess, that could not otherwise be had. There is also a great advantage in raising trees, in a very material point, in an assurance of having fruit that we know we like, by getting graffs, or buds, from trees of which we have tasted and admired the fruit.

In a nursery, flocks may be raised for fruit trees, brubs propagated by suckers, slips and cuttings, and flowers of the biennial and perennial forts may be sown, bulbous offsets planted, and thus a slock may be readily provided for surnishing any part of the pleasure ground. For all, or some of these objects, a spot might be allotted, if it were only the cool corner

Supposing even only a little spot is made use of for a sew flowers, shrubs, &c. let them be duly attended, to weed, thin, water, trim into form, support, shelter, and in short nurse, but yet not to bring any thing up tenderly, as too much, or long cover in winter, exposes to risk when it is taken away; the plants not being able to bear then even a moderately cold air. A low

part of the garden, that has not too much fun, is best for a mursery; if not overshaded with trees.

Suckers, flips and cuttings of any kind, should be attended to for forming a proper head; shortening the shoots, and keeping a clear stem below, and the roots free from suckers. Two years commonly sit suckers for planting out, and three years slips and cuttings. It is a good way, to fasten the two latter, if not the former, to sticks, that the wind, &c. may not loosen them, and prevent their rooting.

Large plants, as young trees, &c. should be tied to stakes well fixed, at first putting out for the same reason. These should be seen to from time to time, that they remain fast; as also, the mats or cloths, that may have been put over hoops to shelter exotic seedlings, &c. from heavy rains, or severe frosts, for the wind

has great power over fuch coverings.

foot

Wil

the

The foil of a nursery should be dry, free and in heart; but not much enriched with dung, lest a rank. ness of food give too great a freedom of growth, and a habit in the plants, which not being indulged by a like soil afterwards, disappointment ensue. A dungy soil also encourages worms and insects, to the injury of seedlings, and makes young plants more liable to be cut off in a sharp winter; too rank a soil, also, prevents the juices of plants from being properly digested, and so they are less fruitful.

On ground defigned to be fown, or planted in fpring, if it needs refreshing, lay on a little well con-

fumed dung towards winter. See page 46.

A nurfery should be laid out into beds of about four feet wide, with alleys of about two; and thus all the work of it will be done conveniently, and the plants will have free air to strengthen them. In the alleys may be buried some dung, which will be at hand, and useful, when consumed by time and turning over, to

dress the beds as they may need it.

Stocks for graffing fruit, are raised from fuckers of plums, cherries, codlins, crabs, pears and quinces; and sometimes from cuttings of codlins and quinces; but those stocks raised from feeds and stones are much best, if we consult freedom of growth. If fucker stocks grow ever so well, they are apt to put forth suckers, which is not only a troublesome circumstance, but exhausts a tree, and prevents fruitfulness. It is to be understood, that the graff will (in some measure) partake of the nature of the stock; therefore soft, mealy fruit, ought to be propagated on austere stocks, and the contrary; tender, delicious fruits designed for forcing, should always be on smart stocks, or they become insipid.

Though crab flocks for apples are mostly used, yet the ripe black seeds of any other smart eating apple may be sown, either in autumn or spring. Sow in autumn, (October or November), and if this sowing fails,

auails,

he spring may be adopted towards the end of February. At these times, the well ripened seeds of pears, or tones of plums, or cherries, may be fown. The tones of any fort of plum, (damfons excepted) produce stocks for apricots, peaches and nectarines; and hough the white forts are commonly preferred, the red wheat-plumb is excellent for the apricot; of black

blums the muscle is the best.

Those feeds or flones that are faved early, or are to be kept through the winter for spring sowing, (which many prefer), should be preserved from air in dry and: Let them be put in a box layer upon layer, three or four courses, covering the top three inches, and guard against mice. Nuts, acorns and chesnuts are but in the ground at the same time, as also the feeds of various forts of shrubs and forest trees. The tenderer forts of shrubs and trees are indeed best sown in March, or beginning of April; and a gentle hot-bed , to would be of advantage, to bring up the feeds with certainty.

The feeds, or kernels of apples and feat-fown in drills a full inch deep, a foot asunder, and scatthem; or fow at broad cast. But take care not to use the feeds of fruit that has grown on a hollow tree, for

they will not vegetate.

The stones of any fruit should be sown at near two inches depth; and nuts, &c. at three or four. Stones and nuts must be set thin, and rather (as of some advantage) the small end upwards, for here the shoot pushes out, or they may be laid flat. If the beds are own all over, cover the feed with mould previously drawn aside in the alleys; but drills have the neatest appearance, and fome little use may be made of the paces between them the first year.

Prepare the beds by digging the soils well to a full foot in depth, and let the surface be made fine: thus will the roots strike down freely to preserve themselves

and

from drought, wet will drain away, and the young

plants push straight upward: four feet beds are best. The enemies of feed beds must be guarded against as poultry, birds, dogs, cats, mice and froft; the latter by covering lightly with pea haulm or wheat straw, and the former by furze, thorns, or brush wood, an traps. If any hares, or rabbits, get at a nursery, the make fad havock in sharp weather, by barking the young plants; therefore, guard against them, and larger animals by good close fences, which will all

keep out tharp winds.

During the first year, they should be kept moderately cool, by watering in dry feedons, or laying moss, or some short litter, over the beds. And as to weeding though they must not be smothered, yet some small weeds may be fuffered to grow in fummer, as the help to shade the plants, and keep the ground cool Seedling trees are very apt to suffer by drought. This them in the summer, after rain, from two inches to three or four afunder, according to their nature; and at the end of the year (i.e. when a year old) thin to from nine inches to a foot afunder: those drawn may be planted out at the fame distance, or at least the best of them; and those left should be re-planted the secon year, left the roots firike too much downwards. The first winter, they ought to be protected from seven froffs, by some light dry litter, which remove in mile weather. At all times, except winter, if the roots of young plants are diffurbed by any means (as pulling we thing weeds, hoeing, &c.) fettle the mould about them allby a good watering.

Stacks defigned to grow for full flandards, should be the fet in rows, three or four feet afunder, and at one foot all and a half in the rows; or if fet at the before-men it. tioned distances, they may be transplanted again, and ther year or two, wider. Rows for dwarfs need not to be fo far afunder as those for standards: but before was they are planted, the fide shoots must be trimmed of one 1,1

In default of these naturally dwarf-growing stocks, those raised from suckers are sometimes used, as less likely to grow off freely than seedling stocks. Layer also are proper for dwarf stocks, and they are commonly to be had from the cadlin; all layers must be

carefully taken up to preferve the roots.

For pears, dwarf stocks are railed from quince cut tings, layers, or fuckers; but as quince shoots are commonly of a weak and crooked growth, the stocks from pear feeds are mostly used. But suckers may be obtained from pears, quinces, &c. by cutting down an old tree within a foot of the ground, and these being planted out for a year or two, become good flocks If the fuckers, or shoots, lay high, they may he earthed up to induce them to strike. But suckers will be often forced, by only cutting off the top of an old tree, which is an experiment to be recommended, in pears particularly) as there will be formed a new head and an opportunity given to graff for another, or better fort. And if there are no luckers, there may be low-placed shoots proper for layers, of those trees that will thus firike, and most trees will, if not the first, perhaps the fecond year.

Stocks from suckers, for dwarf plums and cherries, are in one sense better than those raised from stones, as being less free in their growth: and the common racherw and the black are to be preferred for stocks, who ther as to suckers or seedlings. If suckers of any tree grow at a proper distance from the parent stock, they may be graffed or inoculated without removal, till wanted to plant out for fruiting, i.e. in a year or two Suckers that are for stocks, should always be planted out in autumn, and stand (at least) to the following spring or summer, twelvemonths before they are used springs or summer, twelvemonths before they are used springs, peaches and noctarines are graffed by inoculation on plum stocks, but rather on those raised from stones, except for apricots it hardly signifies. Stocks of the wheat plum, or the muscle are the best. Sigs, quincing

and

and mulberries (as fometimes codlins) are raised from suckers, layers, and cuttings, without graffing; but from layers is the best method, being more sure than cuttings, and more fruitful than fuckers, and in one year they will be rooted. The feafon for both cuttings and layers (a little before or after) is October, though February is rather better for the fig. The layers from fig trees must not be taken off till the beginning of March, as when planted in autumn they may die; other layers flould, however, be then removed.

Medlars are graffed on pear or crab, or fervice-tree flocks; but more commonly upon medlar and white thorn stocks; though the fruit (on the last at least) is

not reckoned fo good.

Grape vines are generally raised from cuttings and layers, (sometimes from buds) either in autumn or spring; but for cuttings rather the latter; and if the vines are pruned in February, or before, lay the cuttings by in dry mould or tand, till March of April. Place the layers in the ground, about four or five inches deep, leaving two of three eyes out. The cuttings should have three or four eyes in the ground, and only one out, or be about a foot or fifteen inches long, and placed a little aslant. Cuttings should have a knot of the old wood at bottom, for those cut off above, though, they may strike, will not produce so good, or fruitful plants; they are also best taken from the lower part of the tree, the wood there being the most ripened. Vines are best raised where they are to grow, by opening a hole, and placing two cuttings in, one of which is likely to answer. Keep it to one shoot, and cut down to two eyes in autumn. Keep to two shoots the next tumn, and then the vine will proceed with vigour, and bear well.

Chefnuts are raised by sowing those that are importea, three inches deep, and four afunder, in rows fix inches part; where growing two years, let them be planted

out half a yard apart, in rows a yard afunder. When five or fix feet high, they may be moved where they are to remain: If the feed is good, it will fink in water.

Walnuts are raised from well-ripened nuts, sown either in autumn or spring; and if the latter (which may be rather best) preserve the nuts in their outer coats, in dry sand. These trees are best but once moved, and their tap root preserved, if for timber, with the head as entire as possible; but if for fruit, the tap root should be shortened, to prevent the tree mounting, and the head may be cut, to accommodate it to the root, as to size. The walnut likes a dry soil, and if gravelly, it does best; and though walnut trees are many years before they come to bear, yet if it were only for the wood, posterity would have reason to commend the planter of them.

Filberds are raised from nuts, or suckers, and layers, the latter of which is the best method; or they may be graffed on the common nut tree. The nuts sown in autumn, or kept dry in fand till February, produce fine trees, but generally differ a little from the forts sown, and make a variety generally for the worse. Nuts

like a cool foil.

Gurrants and gooseberries are raised principally from suckers, slips and cuttings, but best from the latter. When from seed, it is with a view of obtaining varieties, and hence the many sorts of gooseberries in some catalogues. Use cuttings, or slips, of the last year's wood, from fruitful trees, about nine or ten inches long, and set them sour or five in the ground, half a yard asunder; train them to one shoot, (or at the most two,) the first year, and the next head them down to six or seven eyes, when a fine head will be formed the following year, and in the autumn they may be moved where they are to fruit.

Barberries are raised from suckers, layers, cuttings, or feed sown in autumn or spring. The latter mode of propagation produces the finest shrubs, with the largest

fruit

fruit, though it is feldom practifed, suckers being gene-

rally plenty.

Raspherries are almost universally propagated from suckers, being always abundant; and as this saves a year, and seed produces varieties not desirable, sowing is not to be recommended: This shrub is rarely brought into the nursery to obtain strength. See page 38.

Strawberries are raised from seed, offsets, and runners, but almost universally from the last; plants from seed produce the finest fruit, and sometimes a variety that is superior to the original. It should be sown in pots, or boxes in March, or April. This method is particularly to be recommended for the alpine, chusing the

largest and most conical for seed.

The young offsets of the present year, slipped in autumn, or those of the last year (which will be better rooted) flipped in spring, will do for plants, cutting off the flicky parts; but the first runners are more commonly and properly used; and to have these fine, the runners beyond should be pinched off in time. Offsets, early in fpring, and forward runners in fummer, (as soon as rooted in June,) may be planted out in cool ground, at fix inches diffance, by way of a nursery, in order for making new plantations towards the end of September, or in October. This is thought a good way by many, but it is feldom practifed: Let the summer plants be well watered till rooted, and lufter no runners to proceed from them. The common method is to let the runners remain till September, and then, as early in the month as may be, to drefs the beds, and felect the strong and most bushy-rooted sets for forming new beds: It would, however, be an advantage both to the old stools, and the young plants, to suffer only the first or second runners to remain for the purpose: Thus their own beds will be the nurfery for them; and except the foil is worn out, (perhaps,) the best. See page 38.

The raising of FOREST TREES is rather beside the purpose of this book. They have been mentioned as to the time of *sowing*, and their treatment is in a great measure the same as for raising *flocks* for fruit trees; so that to those who would do only a little in this way, much more need not be said.

Forest trees are often lest to grow thick on the seed bed, and only thinned a little in the autumn sollowing, and so from time to time as they get bigger; but a little thinning should take place in the summer, by drawing, when the ground is moist. If the soil that seedling trees are to be planted in be poor, let them be raised in earth somewhat sandy, and at any rate not in

a rich dunged soil.

When young men take to gardening and planting, it is an happy circumstance, and they should lose no time in the business; for it is a thing that persons advanced in years have often repented of. It produces considerable satisfaction, and a peculiar pleasure, in the evening of life, when a man can point at good trees, and say, "These are of my own planting!"—but it were a superior thing to add, "And of my own raising too." Let young planters resolve, therefore, to raise their own trees, especially of the farest kind. "There is no better, or cheaper way of raising woods and plantations, than by sowing the masts or nuts of timber trees, where they are always to remain, and this is best done in spring."

It is to be observed, that the wild service, hawthorn, holly, and ash keys come up the second year; but most other seeds of trees the first. Ash keys, however, (and probably the others,) if they are buried in a pit with coal ashes sisted fine, or in a sandy earth for a year,

will come up the first year they are sown.

To have good feed of the various kinds, is a thing too little attended to; but on which evidently depends much. It should be well-ripened, and the produce of fine healthy trees from the top, or outside branches; withal,

the d as reat

; ıl,

withal, not growing near dottrel, ill-conditioned ones, the farina from the flowers of which might impregnate those of the good tree, and give its feed a degree of degeneracy. Let oak acorns be thrown into water, and those only used which fink quickly;—they should be kept a while to harden, but not too long out of

ground, as they foon fprout.

In the management of a nursery, the young plants of trees and shrubs should be dug round once a year, by a downright cut of a sharp spade, a little distance from the stems, nearer or farther off according to their age, to shorten straggling roots, and produce new ones more at home: Let this be done in October or February; the former time is belt for the older plants, and the latter for young ones. The spade also may be drove under them to cut off the tap roots, where it is not an object to preferve them. By this practice, a good, full, brushy root will be obtained, fitting plants for a profperous removal; but it should be done a year before transplanting. It improves also the soil. Evergreens in particular would be fafer to move, being thus treated; and if only to be moved from one part of the grounds to another, balls of earth will hold well to them. Immediately after the operation, a found watering will be proper to fettle the earth to the roots, except the ground be quite moift; but this work of digging a nurlery is belt done when the ground is dry.

# SECTION VII.

#### OF GRAFFING.

RAFFING, (or grafting,) is the infertion of a cion into a stock, or stem, raised for the purpose, and is necessary to the ensuring of good fruit; i. e. to have

the same (or at least with little difference) produced on the new tree, as that of the old one from whence the graff was taken: It is sometimes performed on the branches of trees, and may be on the roots, a piece being raised out of the ground for the purpose

ing raised out of the ground for the purpose.

If the feeds of fruit were left to grow up to trees

without grafing, they would produce a different kind from that they came from; by chance a better, but most commonly a worse. The varieties of fruit we have, were obtained partly from seedling stocks, without graffing, and partly by an accidental difference,

that the stock, or foil, may have given.

Graffing is like planting upon a plant, for though there is a union of the parts, there is in fact little other communication than a root has with the ground. The cion, or bud, draws nourishment from the stock, but no other than is properly adapted to its own peculiar pores, which by a chemical process (suppose by fermentation in its little bladders, or cells) it alters, so as to become exclusively its own. A great variety of fruit is produced by graff-planting from the same kind of stock, (and that perhaps a mere crab,) just as a great variety of plants are from the same soil: By this means also, some forest, and many ornamental trees and shrubs are propagated, and thus their particular varieties preserved, as in all the variegated sorts, &c.

The art of graffing is a very curious discovery, and though it requires some ingenuity to perform it, a sew trials may make it familiar, and it will prove an agreeable source of amusement and satisfaction. By being able to graff, young trees may be always at hand for replacing old, or unsuccessful ones; and the pleasure of obliging a friend from our stock in this way, is pe-

culiarly gratifying.

Skill in this ingenious art is clearly best obtained by feeing the work performed; and at first trial, to have an adept at the elbow, would be a great advantage. There are few gardeners, (even by profession,) howVII.

Cr,

ever, that practice this work, owing to the great number of nurserymen ready to supply trees. But though they raise fine trees, much disappointment has often happened in dealing with them (particularly in the sort) which might be avoided, by a man's being able to raise good trees for himself. Directions precisely descriptive of the business of graffing, are therefore here attempted, and if once understood, trials should be made without minding the discouragement of a few failures; for practice will make perfect.

Proper flocks being ready, and cions, or buds procured, there will be wanting a good sharp narrowbladed pen-knife, and a sharp smooth-edged pruningknife, with some well wrought loam, or clay, and some good new bass, or strong yarn. The clay should be made up as morter, mixed with short hair, or sine chopt hay, with a little horse dung, and prepared a day or two before-hand; or longer the better, being

beat up afresh with a little water every day.

The first thing to be done is, to cut off the head of the stock at the proper height, and in a fair part of the bark, making a smooth flat top: If the stock is too strong for the knife, and a saw is used, it must be smoothed with the knife after. The properest size for stocks, is from half an inch to an inch diameter, a little more or less, however, may do. When a stock is too little, the cion is apt to overgrow it, and when too big, the cion does not so well, or so soon, cover the stock, as might be wished: yet stocks of any size can be used by one mode of graffing or other.

Dwarf trees are to be graffed within fix inches of the ground, and flandards as high as the flock will well bear, confidering whether they are to be half or full flandards; the former at about three or four feet, the latter at five or fix. But trees designed for flandards, may be graffed, or inoculated at a lower height, the graff being trained to the desired length, by keeping

it to a fingle stem.

П

al

fe

h

that

The cions should be healthy and strong, (not however of luxuriant growth,) and taken from the outsides of fruitful trees, where the juices of the wood have been properly digested by sun and air: they should be taken (if it may be) from trees just in their prime, or at full bearing, and not before. Let them be cut two or three weeks sooner than wanted, and if kept longer they may not hurt, for they had better be cut a little too soon, than too late, at sull length, without any side shoots.

Let the cions of pears, plums, and cherries be cut from the middle to the end of January, and at farthest not beyond the middle of February; the feason must, however, somewhat govern. Keep them all over in dry mould, close under a south wall, or some shelter, covering them with straw in wet or severe weather. Some preserve them in a cool room, where they will do without mould, but it would be better to set them up an end in a garden-pot, with mould, or sand, nearly dry.

Cions cut early are prevented from getting too forward in bud; and if the buds begin to start, and look white, they seldom take. By having them as long as they may be kept before used, the sap of the stock gets in forwardness; for it must first begin to stir, and so be ready to push itself quickly into the cion, (now somewhat exhausted,) to form a union with it.

The middle of cions is fittest for the purpose; but do not cut off the tops till they are brought out to graff, for they keep best in length. If cions are to be transported to any distance, let their ends be stuck two or three inches in clay, and so matted round in a bundle; or, if wrapped round with a fine hay rope, and smeared over with cow dung, clay, or a strong earth, they will not soon wither.

Some gardeners fay, cions should be only of the last year's growth, and others, that the wood of the year before is best; but it is so far a matter of indifference,

that they will take much older, though (perhaps) not fo certainly. As a medium way, if a little of the former years wood be cut with a cien of the last, and this elder wood be used for the part graffed, it will be found to answer, in covering the stock sooner; though it must be acknowledged, that all new wood is the common practice of those who raise trees for sale; which circumstance is ordinarily a presumptive proof of right. However, if wood of a year's growth is not strong enough, then, at least, some of the old wood ought to be cut with it: and the bigger the stock is, the more this practice commends itself, as the barks will be somewhat more equal in thickness.

Proceeding to graff, take off a little of the lower end of the cion first, and then cut it in length, so as to have three or four eyes to appear above the claying: two eyes will be sufficient for a standard, but four is better for a dwarf that is to be trained. In cutting cions into lengths, let the top eye be just in front, or just behind, but rather the former. Use not (except upon necessity) the upper part of a cion, as the wood is too raw for the purpose, and will be shrivelled; yet strong cions (properly incerted) seldom miss through drought: indeed they will take sooner than if quite

ffesh cuel

The time for graffing is usually from Mid-February to Mid-March; but in a forward season sooner, and in a backward one sometimes later.

CLERT GRAFFING has been the most common method of propagation, and though it is not the neatest, yet it is a certain and easy way to young practitioners. The stocks for this mode of grassing should be strong, about three quarters of an inch diameter, or more if it so happen; but it may be used with very young stocks, having cions of like thickness.

Cut off the bend, as before directed, for as to have (on the funny fide) a finouth part in the flock, where the cion is to be placed, and cutting a part of the flock

off slopewise, opposite to this place, leave the top, or the crown of the stock, about half an inch wide.

Then cleave the flock with a strong knife, or thin tharp chifel, about two inches deep, as near the middle as possible, so as not to divide the pith, and if any roughness appears in the slit, smooth it off with a pen-knife; but fomething of the wedge kind must be put into the flit to keep it open to receive the cion, leaving proper room to put it in. Cut the cion on each fide to the form of a wedge at bottom, an inch or more long, making that fide which is to be placed inwards in the stock, thinner by about one third. Put the cion in, so that its bark, and that of the stock be level; and if the bark of the flock be thick, let the bark of the cion fink in a trifle, as the current of fap that unites them, runs betwixt the bark and wood. The cion being placed, take the wedge out that kept the stock open; yet if the stock be to strong as to pinch the cion too hard, ease it by a little bit of dry wood to be left in the cleft; fo, however, as not to loofen the graff, which must be held firmly: or if the stock be very strong, the wedge of the cion may be nearly of equal thickness, inside and out, which eases the barked part.

The graff must be nicely whipped round with wet bass pulled tight, and the whole clayed over to an inch above and half an inch below, smoothing it off taper, with a trowel, or knife, dipped in water. And as this is done with a view to keep out wet, sun and air, if the clay falls off, or cracks, it must be immediately repaired, till the season comes to take off the bandage, which is about Midsummer, or rather sooner: yet at this time some clay thould be still kept on the top, to secure the cleft from wet, and so continued till the

cleft is grown up.

If it is defired to put in two cions, to form a tree for the wall, or espalier, there should be two clefts parallel to one another, one on each side the pith. Some

1

10

ut

put in two cions, merely in case one should miss; but it is not adviseable. It need hardly be observed, that in this case the crown must be left whole.

With respect to the time of performing this work, remember that what has been said relates to pears, plums and cherries: apples cannot be graffed till the beginning of March, or later, as the season is, even

into April, for the fap must run.

WHIP-GRAFFING has the advantage of cleft-graffing in neatness, and not requiring the stocks to be so old by a year or two, as very small ones will do in this way; for the stock is directly covered by the cion, and it takes with certainty if properly performed. Cions suitable to proper stocks cannot however always be had. Stock and cion are to be both of a size, or rather nearly so, is better, the stock having the advantage in bigness; for thus it is not so likely to be overgrown, as it happens when the cion is of a more free nature. When the stock is overgrown by the cion, it will give it some opportunity to thicken, by slitting the bark through downwards, in two or three places. This circumstance is not, however, material in dwarf trees.

Having cut the head of the stock off, and the cion to its proper length, slope the lower end of the cion about an inch and a half, and to a point; then cut the stock to answer it, (the cut of the stock however may be a trisse wider and longer) bark against bark, and tie them together exactly to their place, and clay it. But for the greater certainty of keeping a cion to the part, cut it so as to leave a small shoulder at the top of the slope, and the stock so as to leave a narrow bit of its crown to answer it, and to hold it.

There is a fort of whip-graffing that has been denominated flicing, or packing, which differs only from the one just described, in that the stock is of any size; and this is performed by cutting the cion to a face, as before, and then taking off a slice from the (beheaded)

flock,

fo

stock, choosing a gibbous part of it so as exactly to correspond with the cut-surface of the cion, taking care to fit them so that the cion may stand erect (or nearly) when clapped to. Shouldering is commonly

practifed also in this way.

GRAFFING IN THE BARK, which is formetimes called crown graffing, is perhaps as good a way as any, both for ease of operation and certainty of success; but it will hardly suit any other fruit than apples or pears, as other cions will be past use (most likely) before the bark of the stocks will peel, as the time for this business is towards the end of March, or beginning of

April.

The head being cut off, make a strait slit down and through the bark from the top, at the place destined for the graff, which should be rather foutberly or westerly. This score down the bark, should be nearly as long as the flope cut of the cion, which may be one and a half; or two inches. Loofen the bark a little at the top of the fcore, and then with some smooth instrument rather of dry hard wood, ivory, bone, or filver, than iron or fleel, open the back fufficiently to receive the cion, by pushing the instrument down a trifle below the bottom of the flit. This instrument thould be thin, tapered and rounded towards the point to fuit the shape of the cion's face; one fide of it flat and the other a little convex; the flat fide being an plied to the wood of the stock; let it be rather narrower than the cion, that it may not loofen the bark too wide.

Cut a bit of the bark of the cion fracth off at the bottom, that it may not turn up in pulling down. It will be proper to cut the cion with a finall foodler, to rest upon the stock. And because when the cion is in, it will bear the bark up hollow from the stock, score the bark on each side the cion, so that it may fall close to the stock, and to the edges of the cion. Bind and clay neatly. In this way of grassing there is a fort

fort of agreement between the cion and stock necessary; the cion not being too big, or the stock too small, to prevent a proper bedding. If more than one cion be not put in, the stock on the opposite side to the cion should be sloped up, about two inches in length; to half its thickness.

This way of graffing is used most properly with frong stocks; and sometimes is applied to large branches, and even trunks of old trees, to change the sorts, or renew the wood. In proportion to the largeness of which, from two to five or fix cions are put in, and sometimes of different sorts; and if the stock be large, the more the better, as it heals oven the sooner, and as they insure the life of the stock, by receiving and carrying off the sap; in which respect a single branch of the head of an old stock may be left on, for the sap to pass off by when it begins to stire.

Having inserted the cions, and bound them, clay the top of the stock well, so as to shoot off the wet. In this way of graffing, the cions are liable to be disturbed, or moved from their places by strong winds, and the best preventative is to tie small long sticks to the stocks, and then the cions to them, taking care to place the sticks so as not to force the cions; and as the shoots proceed to push they may be fastened to the sticks also, and so grow two years, when nature will need no

farther affistance.

SIDE-GRAFFING is done in the bark, much like insculption, a cion being inferted inftead of a budy but remember, there must be a fluent sap first: i.e. the bark must part readily from the wood, before this mode of grassing is attempted. The bead of the stock is not to be cut off, only thinned a little if it be big, and the side shoots taken away. The bark of the stock, where the insertion of the cion is to be, must be cut through in the form of the letter T, as wide and as long as is sufficient to receive the cion, cut as before, with a slope sace of at least an inch long, taking advantage,

clo

advantage, (if it may be) of a part of the stock, that is a little gibbous. Let the bark of the stock be neatly raised to receive it, but yet no more than ne cessary; a little bit of the bark may be sliced off the part that is over the cross cut, to receive the cion the better.

Approach Graffing, or inarching, is performed (in April or May) when the stock we would graff, and the tree we would propagate, grows so near together, as to be brought conveniently into contact, and the nearer the graff and the stock are of a size the better. This mode of propagation is esteemed the surest of all, as it will conjoin branches of trees which are scarcely congenerous in their nature; and in truth, some things cannot be so well propagated any other way. It is a method that is, or can be, seldom used for common fruit trees; but if any one wishes to try the experiment, the stock or stocks must be planted at least a year before, first making the soil good, as it may need it, being so near another tree, for it of course must be close.

Plants in pots or tubs being easily brought together, are frequently propagated this way; so that inarching is used much in green-houses and hot-houses for various things, as oranges, lemons, pomegranates, jasmines and vines sometimes: oranges and lemons thus treated in May will be united by August.

The method of inarching is, bend the best situated young branch of the tree or shrub to be propagated, to the stock to be graffed, and having determined on the part at which most conveniently to fix the shoot; cut the bark of that part of the shoot off, with nearly half the wood, (not to touch the pith) to the length of about three inches for a strong branch, or less for a weaker. Then cut exactly so much of the bark and wood of the stock off, as will receive the cut part of the branch, or shoot, so as to bring bark and bark in contact in every part; and if the contrivance of lipping be used, it will secure

pen ground, fix a stake to tie the work so that the wind may have no power over it; a tie also to a neat tick may be proper for those inarched in pots, &c.

As foon as the graff has taken, which will be probably in four months, (except in the harder woods,) et the head of the stock be steadily cut off with a keen mife, three or four inches above the binding, which hen removing, bind and clay again, to remain about month. In March following, cut off the branch rom the parent close to the graffing, and also the stub The head of the flock is of the stock that was left. ometimes cut off before graffing, in which case a loping cut half way the thickness of the stock, is to receive the cion; but, here the graff and the stock must be both of a fize, or nearly so. There has been this distinction made, to call it inarching when the head s cut off, and approach graffing when it is not. Gardeners mostly prefer the former method.

Budding or inoculation, though here last mentioned, is the most considerable mode of propagation, and is a pretty summer business. Apricots, beaches, and nectarines are always propagated this way, and plums and cherries may be. Pears are sometimes budded, and apples have been, but the success is uncertain. Not only fruit, but forest, and ornamental trees and shrubs are inoculated. The branches also of trees as well as stems are sometimes budded, which is best done on two years wood, though it may be on both younger and older.

Inoculation begins as foon as good shoots of the present year can be had, so that the season may be reckoned from Mid-June to Mid-August; but about Old Midsummer, or rather after, is the usual and best time for the work: it should be done in a morning or evening, (the latter rather best), except the day be

cloudy, when any part of it will do.

Apricots

f on 7

> on ess

> ot

ea

V

ęa

fe I

ru

e

ur

ar

lor

pe

nis

Apricats being first ready, the budding season begin with them. The flocks to be used are those of the plus (raised from stones or suckers) when half an inch thick a little under or over, and the operation is to take he place from four to eight inches from the ground.

Peaches and nectarines are propagated on the fame under the fame under the same under the fame under the fame

fort of stocks; but if the plum stock is first budde with an apricot (very low), and when of proper fine budded with a peach, and especially a nectarine, the advantage is reckoned that it takes best so, and come to a better bearing, producing an improved fruit, an particularly the red Roman nectarine. Apricots may a expected to be less luxuriant by double-budding, in which case the first bud should be of the Brussels fort.

Plums and cherries may be inoculated on fucker stocks of any kind; yet if a free growth is required (as for standards,) stocks raised from stones are best i. e. plums on plums, and cherries on cherries, though ak

they will take upon each other.

Pears, if for flandards, should be inoculated on pear flocks, and on those raised from seed, rather than suckers, but if for dwarfs, quince stocks may be bet used, to keep the trees from growing off too fast, and so getting soon too big for their allotted space; white ng thorn stocks are sometimes used with the same view, but the fruit gets stony.

Stocks for budding dwarfs should be three years old; but for flandards four or more, though small stocks and may be budded for standards also, (as mentioned before partif the shoot proceeding from the bud be trained to a ray single stem, till of sufficient height to be topped in the order to form a head. Standards should be from three gratto seven feet high, before they are topped; according to the height they are desired to be a feet high. to seven feet high, before they are topped, according to the height they are desired to be of, as half or full sized; but dwarfs for training can hardly branch of second to the or fix inches, or less and too low, being budded at five or fix inches, or less from the ground, the shoot from the bud should be cul shortened (at a year's growth) to five or fix eyes, or

egin four that are well placed; i. e. with a lateral direcplus on for the wall.

Though the longer inoculation is deferred, the riper
take the shoots will be for furnishing buds; yet there is this
dvantage in beginning as early as may be, that if the
same udding appears not to have taken fam udding appears not to have taken, the work may be adde one again before the season is out. Or, to insure such that it the fam of the case of the season is out. Or, to insure such that it is direction under one another) and if both fail ome his year, the stocks may do again the next, as the eads in graffing by inoculation are not to be cut off all the spring following, because the inserted buds do which of push till then, when they will grow off apace: In very early inoculation, the bud may shoot the same very early inoculation, the bud may shoot the same ear; but it then comes weak, and will hardly endure sired severe winter.

Let the ciens to procure buds for inoculation, be

ough aken only from the outside branches of bealthy and ruitful trees. If early budding be attempted, it will e proper to cut off some spare shoot, (not fit for the surpose), to try first whether the bark will yet readily part from the wood.

The feason being right, and the cions at hand, hav-

pear than

bel and

, or

white ng a sharp narrow bladed knife, and neat tough wet iew, pajs, set about the work advoitly, for the quicker it is lone the better; but "make no more haste than good from such as the such a done the better; but "make no more haste than good old; peed." Keep the bud, as much as may be, from sun ocks and wind: they must not be taken from the upper part of the cions, as the bark and buds there are too to a taw. If cions, or buds, be brought from any distance, they should be conveyed in damp (not wet) moss, or have grass, and never kept above a day and night, but the ding boner they are used the better.

Before the buds are prepared, get the stock ready to off seceive them, by taking off lateral shoots, leaving an less uncut single stem. At the part fixed on for the inequality of the culation, (which should be smooth, and rather on the north

north side) cut the bark through to the wood, in son thus T, the cross and the down slit being of the lengt necessary to take in the bud, which may be cut with from one to two inches of bark; putting the point of knife (or some instrument rather not of iron or steel in to the top of the down cut of the stock, raise the bark all the way to the bottom, so that it will just receive the bud easily. There are knives made on purpose so budding with slat ivory hafts.

To procure proper buds, put your knife in (suppose about three fourths of an inch above the eye, and with slope downwards cut the cion half through, then do it at the same distance below the eye, and sloping it upward cut up the middle of the wood, till the knife meets the upper incision, so the eye will be directly in the middle.

The next step is, to separate the wood from the bark, which is to be done thus: with your nail, or the point of a knife, loosen the bark at the top, and strip it from the wood; or rather with a swan or large goose quill, made in the form of an apple scoop, (having a regular smooth edge) push it down between the bark and wood, pressing against the wood.

Examine the inside of the bark, and if there is a cavity just behind the eye, or bud, it is good for nothing, and another must be procured; for the cavity shews, that the root of the bud is with the wood, instead of being with the bark.

The leaf that grows by the eye is to be cut down to near its footstalk, so as to leave only a little bit of it to hold the bud by while inserting it in the stock.

See that the bark of the stock is loosened a proper length and breadth, and if, when the bud is put in, it should prove a little too long, cut the spare part off; so that the top of the bud (being squared) falls in strait with the cross cut of the stock. Thus fixed, bind it imiderately tight in its place with the wet bass, beginning at the bottom, and passing by the bud, go on to

VI

form

rards the

the

per , it

d it

to

the

e top, or rather above it. Care must be taken that engt e bud is not hurt, and it is to be left only just starting with the tween the bass: This is the mode of inoculation of mmonly used.

Some gardeners infift, that it is best to cut the bark the stock thus I, and so insert the bud by pushing upward instead of downward, because by

hoots off wet effectually.

Others squaring the bud to an oblong, chap ace to be inoculated, and scoring the stock to its size, it it it out the bark of the stock from within the lines, and it is awing put the bud to the place, bind it in: but great rather satiness must in this way be observed, that the edges of Others squaring the bud to an oblong, clap it to the

he bark do regularly touch.

Another way, and perhaps as good as any, is this: ap the bud to the stock, (the bud being first squared)
the hid rather before it is separated from the wood, and
ore the bark on each side, and across the top; and
and assessment of an inch (or rather more) above the bottom
wing his of the side lines; then take off the bark between
bark he lines, and place the bud, by pushing it down this
iece of bark, (being first loosened) which will serve is a hold it. Bind close, but not over tight. If in this ing, nethod the bud fits exactly, it is a very fure and neat a held in a held i ws, ray of inoculating. As the scoring of the stock is of est done before the barking of the bud, a little allownce must be made, as when the bud is separated from s wood, it will spread a trifle wider.
If the buds have taken, it will be so

If the buds have taken, it will be feen in about three reeks, or a month, by their appearing fresh and plump. is often as any shoots appear below the budding, cut nem off, and also some of the shoots above, if there are off; pany of them; for it is not proper that an inoculated rait lock should have a large head. In a month loosen the dit andage, by taking it off, and putting it on gently gain, for another month.

ffi

ch

In March, cut the head of the stock off with a ke knife, close behind the budding, in a sloping direction some leave three or four inches of the stock above to bud till the following spring, and it will serve to tie to new shoot to, in order to keep it to a proper erect direction. Suffer no shoots from the stock, but rub the but off as soon as they appear.

A few observations concludes this long article of pagation by graffing and budding. Persons designing to graff, are apt to neglect cutting their cions till the get too forward, therefore remember to be in time. To do the work well, there must be good tools, it and particularly a keen knife. Choose as good a do as can reasonably be expected, for bad weather occasion hurry and embarrassment; but defer not too long on a count of the weather. In handling cions, take care their eyes, that nothing bruises them, and particularly the buds used for inoculation.

Some motion of the sap is proper at the time of a graffing, but a free motion is necessary for the mode of graffing in the bark, and as on the sunny side of the stod it moves freest, and is the best aspect as to weather, in sertion of graffs, though not buds, if it can be avoided should be always on a part of the stock inclining to the West. Remember to take off, or at least to loosen, the bandages on graffs, as soon as they have taken. It may be of use to shade the inoculated buds a few days, by least, or a bit of paper. Silver (as a fruit knife) is best to raise the bark with, or any thing is preserable to iron.

Though inoculation may feem the flowest mode a propagating fruit-trees, it proves eventually the quick est; and is the most certain way to produce free growing trees, with a well covered stock. The insertions

bud has also the advantage of a cion, as a failure does of burt the stock so much. Avoid this work in very ot, dry weather.

It is to be advised, that some mark be affixed, (or otch the stock) to be assured of the fort; an uncertainty

which is often a great mortification.

Many words have been necessarily employed in dicting to the business of graffing, but let not that ciramstance deter ingenuity from setting about the work; a few failures prevent perseverance, which will at anoth be crowned with success, and the atchievement a pleasing reward.

Though private persons are apt to think much of the iffiulty of this art, yet the ease, celerity, and certainty, ith which Nurserymen personn it, is great indeed:

ch is the ability that much practice gives.

## SECTION VIII.

### OF PLANTING.

A S so much depends upon proper planting, every attention ought to be paid to it. This business may be arranged under these several heads. 1. The hoice of plants. 2. The act of planting. 3. The bil. 4. The situation. 5. The season.

1. As to the CHOICE of plants. Trees ought to he best of the kind; and therefore no care in raising or caution and expence in purchasing, should be spared that at least there may be a fair prospect of satisfaction. To plant, and after waiting a long time, to be disappointed, is rather a serious missfortune; especially who the work is to be begun again late in a man's life.

Having some confidence that the fort is right an good, the plants must be seen to, that they are healthy, they should appear found as to any external injury. It they are of a squat, weak, bushy growth, there can be little expectation of their becoming good plants; though it may sometimes happen that a tree of poor promise will rally.

Trees graffed on old funted stocks, or that have often been removed, or frequently cut down, seldom grow of well in any soil, and should be rejected. Let those that are purchased be seen to, as nurserymen often have such trees, having remained long on hand.

Good young trees have a smooth, bright, and strait appearance, rather of a robust growth than otherwise; though the most luxuriant are not to be preferred, for their wood is raw, and wants that firmness which is necessary to fruitfulness; they may get off this crude state in time, but the moderately free-growers are best.

Young fruit-trees are the best to plant; for though old ones may sometimes succeed with good management, yet they are liable to stunt, and dwindle off; whereas the former establish their roots quickly, and grow off apace; so that young trees planted at the same time with old ones, generally overtake them in a few years, and are superior.

To have moderate shooting trees for the wall, or espalier, chuse such whose twigs are rather slender, provided they are healthy: they will not only be kept easier within compass, but in general be more fruitful.

10

oro ept

uit-

o be 2. The ACT of planting. Trees taken up for planting should be dug carefully, with (as much as posible) their full roots. Many a good tree has failed merely by being taken up badly, and then planted fo. The roots of fruit-trees are often not only mangled, and too few, but are also put into the ground without my dreffing or care.

The less roots are exposed to the air the better, and he fooner trees are planted after being taken up, the more likely they are to succeed well. Trees properly backed (i. e. the roots well covered) may live out of ground ten days or a fortnight, in autumn, or early in the fpring; but nothing except necessity will justify the keeping a tree out of ground a day longer than can be

helped.

If it be determined for any length of time before hand, when and where to plant, the opening the ground, and exposing the holes to the fun and air, (and if it may be to frost also) will both correct crudities in the soil, and mrich it from the various stores of the atmosphere; this opening should be as wide and deep as convenient,

hat the benefits of the air may be extended.

Some people do the work of planting very idly, as if twere fufficient to fee that a tree has a root, and that t was only necessary to bide it in the ground. Every one who plants trees should stand by himself, or have ome trusty person to see the work done, or the necesary labour may not be bestowed. It is frequently the way (for instance) to dig a hole no bigger than will receive the roots of a tree twifted and forced in; but being thus cramped, and the veffels of their roots diforted and broke, it cannot be expected that such unnaural treatment should answer.

But the above violence is not all; the roots are con-ined as in a prison, (in a tub or a bason) which, if the oil is strong, detains wet, and chills and cankers, if not rots the fibres. To plant well, the roots of a tree The hould have liberty to strike out freely every way, and

t

2

b

d

e

tr

pi

ho ar

th

m

an ab

fw

an

at Fi

rec

alon

the ground well broke for their easy progress. Let hole for a tree be loofened about two feet deep, and wide as will be much more than fufficient to receive the roots in their full spread as they grow, with little no direction given contrary to the original one.

When the tree is to be planted, take out the earth little lower than necessary for the roots, at the dept the tree is designed to stand; then dig the bottom to the full spade's depth. Trim any dead or damaged part of the root clean off; thin it of the finer fibres when the time the tree has been out of the ground, for the fine roots foon die, and if dead, ought not to be on Trees moved only from one part of the garden to and ther, need have but few fibres cut off, but fome ampu tations are necessary to help the sooner to new roots which shortening always forces out. If the root has tap, (or downright spur) it should be cut to the gent ral level of the other roots, and never be left longe than a foot from the highest part of the root. Those great roots that lay aukward, or croffing, should be judiciously rectified with a sharp knife; be cautious duce stronger branches in proportion to the goodne top of the root. Though it be little practiced, it may be low very well to apply some mixture, as of room. very well to apply some mixture, as of rosin and best or

wax, to large amputations: Cow dung may do.

The head of a tree should be somewhat conforms we to the root. Some reduction of the head may take place at the time of planting; yet not all that may be an interest to the solid planting; but he solid alone till the sap stirs at spring, and then care should be taken to proportion the head to the root; and me care leave on a tree too many buds, for a few stout branche are preserable to many weak ones. This is the of sum dinary practice with respect to wall trees, and when their not of all others. See articles, Orchard and Pruning with Sect. 3 and 12.

hole

The hole being made as directed, form a little hillock in the middle of it to lay the roots on and round; clap the tree upon it, and having thrown on a little good and well-broke mould, give the tree a gentle shaking lift, which will let the earth in close among the roots, and bring the tree up towards its proper height; by not doing this, the roots are fometimes turned up at the ends, instead of laying rather downwards: Set the tree high enough to allow for a fettling of the earth, in proportion to the depth it was loofened. Young trees, however, should have their roots nearly upon a level, and so must have their ends raised with the hand, if they are suspected to be too much depressed. mould should be thrown on gently, a little at a time; and if some that is finer and richer than the rest be put about the roots, just to cover them, it would well anfwer the trouble, helping the tree to strike fresh roots, and grow off the faster.

Trample the mould gently about the roots, beginning at the outside of the hole, and so towards the stem. Finally, leave the ground a little hollow on the top, to

receive rains, or waterings.

As to depth, trees in a light dry soil may have the odne top of their roots settled at about five or six inches beaut be low the surface, and in a strong soil about three inches; be or it may be a general rule to plant a tree no deeper than it was before: for trees planted too deep never do well. Always keep the roots of a tree above a heavy take clay, for the making trenches in it will not answer, and any be an unhealthy tree may be looked for. See next article soil. If the good soil is thin, the roots should be almost planted in sight, raising the earth about them. Take do not care to protest the roots of all, but especially of high set trees, from frost the first winter, and drought the first summer. This covering of new planted trees about whether roots from extremes of weather, may be either with good solid turf, litter with stones on it, or stones alone, which by their weight help to hold the tree saft.

Take

Litter should be laid near a yard round, and five or surinches thick, to keep off severe weather. Where plent of moss is to be had, it is a neat material to lay about roots to keep them from drought. If litter alone is last about trees, (particularly against an old wall) mice are apt to harbour in it, and bark them: where such covering is used for winter, move it early in the spring, and supply the place with turs, which will be proper to continue all summer.

Watering is to take place if trees are planted early in autumn, which fettles the mould about the roots, but let them not be fodden with it. Late in fpring water will be fafely and necessarily applied, and must be repeated also if dry weather; but yet with caution, for many new planted trees have been injured (if not killed) by keeping the roots wet. Late planted trees should be occasionally watered throughout the summer: those planted in winter need none.

In planting wall trebs, (the budded part outwards) try in the hole which way they will belt stand against the wall; and if they bave a head designed to remain for training, place it carefully for the branches to be laid to but keep the tree as far from the wall as may be, (suppose eight or nine inches) that the roots may have the more room to strike behind: cut off, or shorten much all roots whose direction is straight towards the wall. Nail the tree to it, that wind may not disturb the roots.

In planting flandards, it will be proper to fix a flattenear the stem to fasten the tree, in order to prevent the roots being disturbed by wind, which prevents their striking out new fibres; rocking about opens the ground also about the stem, and admits frost, by which a tree is sometimes lost, or succeeds badly. This staking is best done while the holes are open, and the roots of the tree seen, as by driving a stake in afterwards, it might damage some principal root, and the hurting a root is to be avoided as much as bruising a branch

ake

Take care to fix the stake firmly, and to tie the tree so with a hayband, that it may not easily get galled. Twist the band close round the tree first, and then round he stake and tree.

In late spring planting it will be sound of good use to take a mixture (in a barrow) of fresh cow dung and he mould, half and half, to put about the roots, which will greatly help to keep them cool, and plentifully to our is them. In default of cow-dung, a puddle of he sisted mould and water will do. Or, if the soil is

ght, mix half mud from a pond or ditch.

Circumstances may occur to make summer planting estrable, if it could be safely done. It is certain that oots quickly strike in summer, and if the head of the ree is a little reduced, and some shading contrived for a while, even wall trees may be then planted with cow lung. But the greatest point in this business is, that he tree be not out of the ground so long as to dry the oots; by some means they should be kept cool, and if ried, put into pond water a few hours before planting. Trees thus planted will not need watering for a long ime, and must not have it, for over moisture might rot he delicate new sibres.

or nothing pleasing can be expected: It should be weet and nourishing; and therefore if not naturally so, t is to be improved by art and labour. Tillage or breaking up a soil, to expose it to the atmosphere, is of much benefit. See article Soil, in the Formation of a

Garden. Sect. 3.

If nothing more can be done at the present, at least make the ground fairly good where the tree is to be et. Two or three barrows of fresh earth, if of a good quality, is far preserable to dung; but if the soil really needs manure, let it be well incorporated by the spade; and work some rotten dung in deep, below the roots, which will be properly consumed before the new roots teach it: much must not be used.

oil

n

tre

oi

1 1

vei

olu

fo

riv

the

un

In the case of only making the soil good for the profent, the first opportunity, (or at least before the room spread far) should be taken to extend the benefit as sar as may be, even to several yards round, and let this work be done deep enough, or as low as the pan made good for first planting, i. e. two seet, or as near upon it as the case will allow. In a sew years this attention should be extended (in bad soils) to where it may be thought possible for the roots to have reached. For want of this, a tree sometimes sails when just come to its full size and principal time for bearing. When roots reach a weak, ill-conditioned, poisonous soil, the tree must sail; and it should be remembered, that the extreme branches of the root are what chiefly nourish a plant.

Fruit trees (though they like a rather strong soil) will not prosper, or hardly grow, in a cold clay; but in a soil that is tolerable above, they may be planted, by improving, or raising this, as the case may require, and cautiously avoiding going into the clay. Some persons have laid stat stones, or tiles, below the root to a considerable distance, which perhaps may answer; but it seems advisable only to do it about a foot square, (or a little more) as this may give the roots a desirable horizontal direction. It has been recommended to do this in all kinds of soil, in order to insure a more superficial spread, than without such contrivance could be expected. If the foil be good, (at the same time strong) above any bad soil, and the roots take to run towards the surface, it is surprising how trees will thus prosper.

When planting takes place fuperficially, let a hillock of earth be laid round the roots, and the tree secured by a stake for two or three years to hold it steady; and keep turf or moss about the root till the tree is well established. The hill may be from six inches to half a yard high; in the latter case, lowering it a few inches every year in autumn till within six of the root.

In

In a foil that trees are found to canker in, and get therwise diseased, it is of no use (generally speaking) wait their getting better; but if there is any spot of a more promising quality, those that are not too old and ar gone may be removed there, and perhaps recover; ut let the root be examined, as well as the head, to cut ut any diseased part. If the shoots should be weak the list year, prune down close the second, and strong wood may possibly follow.

With respect to the foil that suits every particular and of tree, there is some variety of opinions. Geneally speaking, a true loam suits every thing. See

Formation of a Garden, Sect. 3.

The following particulars feem to have a pretty comnon consent. Vines love a rich dry soil, gravelly or andy, if it does not bind. Figs like much the same oil, though they need not fo rich a one: ashes are good n the foil for figs. Apricots flourish in a light loam; out peaches and nectarines should have a somewhat frong loam, and the latter needs the warmer or richer. oil of the two. Pears like a strong but dry soil; apples frong and a cool one, if it is not wet. Cherries, dums, walnuts, and mulberries, prefer a dry, fandy, graveily, or light foil, though they will grow in a stronger; blums do very well in a moift foil, and produce the arger fruit in it, but the flavour is inferior. Quinces fourish most in a rich and moist soil, as by a brook or river's fide, or where a rich wash from finks, or dunghills, runs occasionally about their roots: in a dry soil. their fruit is small, though higher flavoured: It is an univerfal rule, that fruits are forwarder and more grateful in dry foils, but of less fize.

Though the vine be planted in a right foil, yet it will require to be fed and enlivened with some spirituous manure, either in autumn or spring. For this purpose water impregnated with sheep's dung and fresh urine has been used. The top soil being removed, bullocks, or which is best, hog's blood, is sometimes ap-

plied; or it may be let in by making holes with a sinooth sharp-pointed stake, not too near the stem. A little sheep's dung, or that of poultry, dug in regularly every autumn, is a good, neat, standing rule.

4. The SITUATION properest for planting any particular kind of tree is to be considered; for some like a low, some a high, some a moist, some a dry situation; but it is spoken here chiefly of fruit trees. Particularly observe that pears graffed on quince stocks, must have a

moist soil, or they will not do well.

The general situation of a country will in a measure rule; for though England be but an island, it has many climates in it, and certain plants will do better in one place than another, (even within the space of a few miles) as to effects from weather. The difference between hill and valley in the same place, is something, so that in the latter the tender blossoms of trees shall escape, when in the former, unkind winds shall cut them off:—not that valleys are always safe, for they have

Peas fown to stand the winter, in a garden on a hill, and in another only a hundred yards below, in a vale, the former exposed, and the latter well sheltered, will demonstrate what situation will do; for the peas below will live when the others are cut off, and perhaps come in a week earlier, when both survive uninjured.

sometimes destructive blasts from mists.

In very exposed places, especially northwards, little fruit can be expected from the more delicate wall trees; it is prudent therefore to avoid planting in cold places the tenderoft, or the earliest, or the latest sorts. The difference of latitude between Middlesex and Northamptonshire makes commonly a fortnight in the coming in of many things; so that, generally speaking, what is called an October peach, is of little worth in the latter county, though in the former it may do well: Without plenty of wailing for experiment, therefore, do not plant late fruit far northwards of London.

A

The farther north, however, is not a certain rule the productions of the garden being proportionally later; for in some parts of Yorkshire they produce vegetables and fruits, nearly as early as about London. This has been ascribed to subterraneous heat from coal beds, or minerals, acting as natural hot-beds; but it may be attributed simply to a rich, warm, and deep soil, having gravel below it, especially when in a valley sheltered by winds on the cold side.

With regard to fituation, we should consider the garden itself, and not plant choice fruits in a cold or shaded part of it: the aspect must be good for them as well as the soil. From an error of this sort, Vines have frequently been planted and pruned for years, producing

nothing but wood and leaves.

Figs and vines, nectarines and peaches, (as natives of hot climates) should have a full sun here, or little fruit can be expected from them; and Apricots ought to have a good share of it, though they do very well (in some places) against an east wall, and perhaps against a west. An east aspect is not so safe as a south one, as to the embryo fruit at the time of blossoming, nor does it bring the apricots so forward; but the fruit is commonly better: it has the earliest sun all the morning, and the beanest of a gentle warmth asterwards, by the wall, (the sun shining hot on the other side) if the tree is nailed properly close. See Formation of a Garden, articles Situation and Aspect.

From what has been faid on fituation, the young gardener will be led to make some discrimination in planting, and not hope to succeed when working against nature. If his garden is small, let him contract his desires, and proceed upon sure grounds: but if large, experiments and risks are not of much consequence. Favourable and unfavourable seasons make a great difference; but hope should have a foundation, and we cannot expect a fortunate end, without the use of pro-

bable means.

5. The season for planting is a matter of confequence, though some persons are apt to neglect it win should, and do, know better. The proper rule is, to plant as early in the feafon as can be; fo that if the ground is ready, trees had best be put in when the leaves begin to fall, i. e. in October; yet some good planters have recommended even an earlier time than this; and scruple not to plant all the latter half of September, though the leaves be full on. Some trees will form fresh roots in the winter; and those which do not, yet get so united with the earth, and prepared for starting in the spring, that they are ready to answer a supply of juices much more freely than when late planted; and consequently the new shoots must be stronger. Let nothing but necessity put off planting in autumn, except indeed the foil be a cold one, and then the work done early in fpring is proper.

The season for planting in a dry soil may be all winter for deciduous trees, i. e. those that close their leaves; but all evergreens, (except the Scotch fir, which may be planted at any time) should be moved early in autumn, or late in spring, and rather the latter, as they are somewhat uncertain in taking kindly to the ground, especially if the weather is unfavourable at the time of planting. The oak and larch (though deciduous) are removed safest in the spring. In spring-planting always give a sound watering at the time, and if late in the

ipring, repeat it once a week in dry weather.

Let even the meanest trees and shrubs, as currants, gooseberries, and raspherries, have the like attention paid to them as to their superiors; for their fruit will prove the siner, and the argument is cogent for an October planting of these, as they are to bear the next season. Let them be taken up, and planted with care; for the best way of doing every thing ought to be the rule of practice in all cases, and a gardener should follow it above all persons.

Γ.

### SECTION IX.

of shrubs, shrubberies, &c.

WE are indebted to SHRUBS for much of the pleasure we enjoy in our gardens and plantations, and they justly merit every care, though they produce us no (or few) edible fruits. They affish in forming an agreeable shade, they afford a great variety of flowers with leaves differently tinged, and are standard or naments that give us no great trouble.

Of shrubs too little care (however) in general is taken to plant them properly, or even to choose good plants for the purpose; and hence they often fail to flourish, and are mortifying us with a dwindling growth, and unhealthy appearance, when they should have be-

come objects of admiration.

Many shrubs are raised from suckers, others from layers, some from cuttings, and most may be propagated from seeds, which, though the slowest method, generally produces the finest plants. Before they are planted out for ornaments, they should be trained two or three years in a nursery, to be formed into a full and regular shaped head.

Though deciduous shrubs may be planted almost at any time, yet October is much the best month, especially if a moist season; the exception being made as to a cold wet soil, in which all sorts of planting (as observed be-

fore) is best done in spring.

Evergreen shrubs must be cautiously planted, and should not be ventured upon in winter, and even in autumn

th

autumn and spring ought not to be meddled with in harsh weather: drying winds are apt presently to injure their roots. It is a good rule, let the weather be what it will, and the sorts what they may, to expose the roots to the air no longer than can be helped; evergreens should therefore be immediately planted after they are taken up, and their roots also very carefully preserved whole. And if the shrubs are small, and it can be, let them be removed with balls of earth to them, trimming off projecting ends.

As shrubberies, clumps, &c. are often made on poor or indifferent ground, the soil should be previously cleared, well dug, and trenched, and that as long before planting as may be. For spring planting, this work ought to be done in autumn or in winter, that the soil may have the benefit of frosts, and other helps from the atmosphere, which is a circumstance of much conse-

quence in the cafe. .

Tillage not only faves manure, but is superior to it, where time can be allowed exhausted ground. In planting shrubs and trees, it is desirable to do without dung, as much as possible; and therefore a little soot, or turf-ashes, &c. sprinkled over the ridges of trenched ground, is good; and if the trenches were turned over once a month, the advantage would be fully answerable to the trouble.

As spring is, on the whole, rather the fittest time for moving evergreen shrubs, and as the deciduous sorts do then also very well, shrubberies and clumps will properly enough be the work of March, a little earlier or later, according to the soil and season. Light sandy soils should always be planted in good time, and any fair weather that appears settled, should not be neglected: the beginning of April, however, is by some reckoned the best season for planting shrubs. A good medium way is to plant the deciduous sorts the beginning of March; and, leaving places for the evergreen kinds, plant them the end of March, or the beginning

of April. But it were still a better way (if the ground s in order) to plant deciduous shrubs in autumn, and the

vergreen forts in fpring.

If autumn be the featon fixed for planting, it will be proper, before the frost comes in, to cover the roots of hrubs, and especially of evergreens, with litter, and indeed at spring it should be so; for neither frost nor drought should be suffered to affect new planted trees, or hrubs. Let the outside plants of a new shrubbery, towards the fun, be covered about the roots all fum-

mer: Turf will be neatest.

What has been faid of the act (or method) of planting fruit trees, should be observed of shrubs. In dressing the roots of thrubs, thorten them moderately, prune the heads fo as to form them handsomely. Settle the ground to the roots by watering, and leave a little hollow round about them for future watering, if the feafon should require it. Let the taller plants be tied to stakes, as the wind is apt to disturb them, and hinder their speedy rooting.

The proper disposition of shrubs, where there are many to be planted, should be considered in several particulars; for the beauty and prosperity of a planta-

tion depends greatly upon it.

The distances must be according to the fixe they usually attain. Some grow off flow at first, but afterwards get large; but still these should be rather confidered in a middling way, otherwife the ground will be a long time naked. Some forts will require not more than a three feet distance, others four, five, or fix; but as they are finall, when planted, and perhaps much of a tize, the future height and spread are frequently not confidered.

The Istuation, to accommodate them as well as may be, according to their tender or hardy nature, should be attended to; not to plant evergreen thrubs, or the more delicate deciduous forts, on the outfide towards the N. or N. E. and as there may be an irregularity in

the ground, the lower parts and deeper foil will be more fuitable to fome, and the higher and shallower may do

very well for others.

Tender shrubs should not only be sheltered for protection, but be planted in a dry spot open to the sun: Some things will live abroad in a dry and poor soil, that would seldom survive a winter in a rich and moist one. The more towering sorts must be placed behind, and the less so before them, gradually declining to the low growing ones, in a sort of theatrical order: This is necessary in a shrubbery, and indeed all plantations, but more so in the disposition of plants in clumps, keeping the center high, and falling gradually towards the edge. Thus the stems, and naked parts of the higher plants are hid by those before them, and the whole appears to the eye a full scene of verdure.

The feason of shrubs flowering and leasing is a material point to provide for, by a proper distribution, that there may be a sprinkling of decoration every month, in every part. And in this business, an equally dispersed mixture of the evergreen, and deciduous sorts, is neces-

fary to be observed. See Sect. 19.

As to the proportion of this mixture, it will depend upon taste, and the opportunity of procuring the one sort, or the other; but the circumstance may direct (in a measure) whether the plantation of shrubs be about the house, or at a distance from it. In the former case, more evergreens should be made use of, as in sight in winter: generally speaking, perhaps, one evergreen, and two deciduous shrubs, or one and three, may form an agreeable shrubbery for view at all times.

A regularity in planting shrubs is not necessary as to lines, but is rather to be avoided, except just in the front, where there should always be some low ones, and a border for flowers, chiefly of the spring, as summer ones are apt to be drawn up weak, if the shrubbery walks are not very wide. The flowers should be of the lowest growth, and rather bulbous rooted. To-

wards the edge may be planted aconites, snow-drops, rocusses, primroses, violets, polyanthuses, hepaticas, wood memonies, (in particular) dassodils, cowssips, &c. In open shrubberies an edging of strawberries is proper, and the hauthoy preferable, on account of its superior how when in flower; but in these situations the wood frawberry is more commonly planted, as it will pro-

luce fruit with less sun and air.

The management of a plantation of shrubs comes next to be confidered. It should be kept clean, or nuch of its beauty is loft. Let it be frequently hoed and raked, to give it a fresh appearance, and prevent he growth of moss, which spreads apace from the ground up the stems of plants, and thus injures them much. The usual time for pruning and digging about shrubs is pring; but autumn (and early in it) is better, if the plants are well established in the ground, and especially The pruning should not when old and full of roots. be late, (October best) as some sorts are apt to die down; hefe, however, might be left to spring, or only shortned in part: They should constantly be kept free from uckers and luxuriant wood. See pruning of shrubs. An autumn dreffing is particularly to be recommended s lessening the work of spring, the hurry of which seaon fometimes occasions shrubberies to be neglected too ong, and to be but partially attended to.

The fuckers, or young plants, found in digging and ressing about shrubs, are often lest carelessly on the round, but if likely to be wanted, ought to have their oots buried as soon as possible: Why should they be

uffered to wither, because they may recover?

For hedges about a plantation, (i. e. for the divisions of it) the laurel, yew, and holly, are the principal evertreens; the former as a lofty and open fence, the second is close and moderate in height, and to be cut to any thing, the last as trainable by judicious pruning to an impregnable and beautiful fence. Deciduous divisions are best made with the small leaved elm, or the hop hornbeam,

rei

eft

ing be in ing

vit

be i

the

to I

con

the

ple:

live

lear

hornbeam, as they are tonfile, and of a peculiar neat foliage to the very bottom. If a lofty hedge is wanted,

the beech makes a good one.

Old walls and pales are somewhat unfightly, and if covered with plants are rendered agreeable. The evergreens to be recommended for hiding them, are the laurel, phyllyrea, aluternus, pyracantha, yew, box, and lau-rustinus; but if the aspect of the wall be N. let them be planted late in spring. Ivy, box-thorn, and other climbing fhrubs, answer the purpose: the white and yellow striped loy are beautiful. If a mere summer covering be defired, and the wall is high, bornbeam, (rather the hop) and witch elm, do very well when planted close: filacs, or even black currants, also may do, and will foon come to a cover: But whatever is planted for the purpose, let it be kept regularly trimmed, and trained close as may be to the wall. The gable end of a building may be covered with a pear-tree, or a vine, for though the vine should not bear, it will answer its prime end, and looks well when in full leaf.

and

1 2 ery

ery respectable manner by so doing. Let the work be t about with all speed and resolution; for every year oft to planting is to be lamented, both in a public and rivate view.

What if forest trees produce nothing for the table, no immediate profit, they afford, in their raifing, lanting, and nurling, present entertainment of a very rateful kind; they may ever after be viewed as objects f facisfaction, and posterity will have reason to praise the

vork.

Plantations of forest trees do very much ornament a ountry, and there are some grounds peculiarly situated o become objects of delight in this respect, which ould not be better employed. A place without trees eing destitute of one of the most useful materials for uildings, utenfils, &c. is in truth to be lamented as nfurnished and forlorn. The demand for wood is peretual, and the confumption is great; and therefore a rovision for generations to come, by planting of forest rees, must afford the fincerest (because most difinteefted) gratifications of pleasure to the mind.

Though every one has not ground to form plantaions of any confiderable extent, yet if it were only a ingle tree here and there, i. e. to do what little might be in this way, it would shew a worthy spirit, and make man an honourable benefactor to fociety. Corners of ields might have little clumps conveniently planted, without much expence of fencing. A few trees might be planted in, or rather just without, bedge rows; but these should be chiefly oaks. It is a practice with some, to plant trees in hedges when first made; but they are commonly too small, and so the quick choaks them, and

they never thrive.

The planting of forest trees is profitable as well as pleasing and respectable; and a young planter may live to reap much reward from his labour, or he may leave a valuable inheritance to his children. "The

plantation

plantation and care of timber is like buying the reversion of an estate—for a little money expended, we become heirs to great sums.—In countries scarce of firing, and where poles and rails are wanted, under wood will pay the proprietor triple more value than the best fields of corn, and the oaks among it remain a great estate to succeeding generations." Poor land, that does not answer for corn, would be profitably cultivated in wood; but such ground should be sown, rather than planted. Wet places may be advantageously planted with the amphibious tribe, as willow, sallou,

withy, ofter, &c.

For those who may be disposed to plant forest trees, the following directions are offered:—The manual work proper to this business, may be gathered from what has been already said on planting fruit trees and shrubs; and though plantations of forest trees need not be so nicely attended to as fruit trees, yet the better the work is performed, the fairer is the prospect in growing good timber: a check by an error at first planting is a loss of time, and a damage done to trees which is sometimes never recovered. To give an instance:—the mould is often thrown on the roots of a forest tree in lumps, when if a little sifted earth were used, so as just to cover them with fine mould, the trouble would be amply repaid by the quick striking, and suture strength of the tree.

Ground designed for planting should be prepared as long as it can beforehand, by the use of the plough of spade; and if some fort of previous cultivation, either in carn or vegetables, were adopted, the soil would be better sitted to receive the trees. At any rate, the places where the trees are to be set, should be previously dug somewhat deep, and cleared of rubbish, perennial weeds, twitch, &c. If wet, let it be properly drained, for none but aquatics can do well in a cold and

very moist soil.

In

In open planting for timber, to make only the holes ood where the trees are set, is sufficient, if the soil is ot strong, (which generally speaking however it hould be,) and in such plantations the plough being sed for corn, or some fort of crop to be carried off, he whole soil will be prepared for the trees' roots to read. A plantation of this fort may be constantly inder the plough, till the trees shade too much, and hen it may be sown down for grass, which laying warm, and coming early, would be found useful. The opportunity given to improve a soil by this cultivation,

would infure very fine timber.

But a plantation of trees being made (as suppose of aks) at due distances, and the ground ploughed for two r three years, while they got a little a-head, then it hight be fown profitably, with nuts, keys and feeds for inderwood, observing to thin the plants the second year, nd again the third, till two or three feet afunder in poor ground, and to three or four feet distance if rich. In fourteen or fifteen years, (or much fooner for fome burposes), the ash poles, &c. will be fine, and meet with a ready fale as useful stuff: Afterwards the underwood will be fit to cut, in a strong state, every eleven or twelve years. In the management of underwood, some have thinned the plants while young, to three feet asunder, and cut them down at three years, to about fix inches, in order to form flools, which in about ten years are cut, having produced several stems from each. Some persons have cut seedling trees down at this age to three inches for timber, leaving only one frong shoot to grow from each stool; and thus finer trees are frequently (or rather certainly) produced, than from feedlings not cut down.

The distances of the timber plants, may be from twenty-five to thirty-five feet, according to the foil, or opinion of the planter. If no view to underwood, the above open planting may be made close, by setting first the principals (which should be fine plants) and then

filling

filling up with others that are worse, to within about eight or nine seet of one another. They will at this distance come to fair timber, or may be thinned at pleasure; and even among these, a small crop of underwood might be had, which would shelter the timber

plants, and help to draw them up strait.

As to little plantations, of thickets, coppices, clumps, and rows of trees, they are to be fet close according to their nature, and the particular view the planter has, who will take care to consider the usual size they attain, and their mode of growth. An advantage at home for shade or shelter, and a more distant object of sight, will make a difference. For some immediate advantage, very close planting may take place, but good trees cannot be thus expected; yet if thinned in time, a strait tall stem is thus procured, which afterwards is of great advantage.

For little clumps, or groupes of forest trees, (as elms) there may be planted three or four in a spot, within five or six seet of one another, and thus be easily fenced: having the air freely all round, and a good

foil, such clumps produce fine timber.

Single trees of every fort, grow off apace, and are more beautiful than when in the neighbourhood of others, and particularly firs, pines, larches, limes, walnuts, and chefnuts: the edible fruited chefnut is only good for timber; but the horse is very ornamental, flourishing however only on high dry ground. As to rows of trees, whether single or double, when planted for a screen, they may be set about seven or eight seet assunder, upon an average, according to their nature, taking care to prune them occasionally, from too galling an interference.

Avenues are now feldom planted, but when they are, two good rows of elms, limes, chefnuts, &c. should be set at the width of the house, at full thirty seet distance in the rows; to thicken which, intermediate plants may be set; and also an inner row, to be removed when

ved. nen then the principal trees are full grown. Avenues to

rospects, thould be fifty or fixty feet wide.

The best season for planting the deciduous kinds of prest trees, is the latter end of October, and evergreen orts, the latter end of March; though the soil, whener light and dry, or heavy and wet, should somewhat direct; evergreen trees being to be planted generally with safety, early in autumn, if the soil is warm; ut in all cases trees thould be planted in dry weather, hat the mould may be loose to drop in, and lie close etween the roots, which is a material thing: Trees lanted in rain or mists, are injured by moulding the poots.

Forest trees for planting are generally preferred raher large, and being so, should not be taken up idly, ut with as much of an uninjured spread of roots as offible: yet, free growing plants of about three or our feet high, promise in the end to make finer trees han those that are planted larger. Some say they are est at this size from the seed bed; and others, to have een once planted out, having had their tap roots then ut, and generally speaking, this is the case, as they

ave a more bushy and horizontal root.

In the act of planting, let every thing be done as diected for fruit trees; i. e. the hole dug wide and deep,
he ground well broken, or rather fifted, to lay immeliately about the roots, &c. Let the trees be made fast
y stakes, and litter laid about their roots to keep out
rost and drought. It is of much consequence to take
are that the roots (especially of evergreen trees) do not
get withered before planted. Evergreens do best in a
ry, but deciduous forest trees (generally) in a moist
oil, if it is not wet. Oaks in particular, though at
inst they may appear to do poorly, grow well in strong
noist ground, and make the best timber.

Fencing is the last thing to be considered. If trees replanted where cattle go, their stems must be proceeded from barking and rubbing. The common way

n i

hife

ur

bo

hir

m

of small posts and little rails is well known; but large cattle are not sed where the trees are, go thorns stuck round them, and tied to them, is a cient, and indeed this might do in almost all case. There are various ways, ordinarily known, but whe ever mode is used, let it be at first well executed, a afterwards repaired in time, as often as there is near Something concerning the raising of forest trees will

found at page 78.

Whoever plants forest trees, should take care to do them by proper pruning, and suffering no suckers to main about their roots. Their tops should be keep equal, and not permitted to spread too much in hear branches, but trained in a light and spiral way; alway preserving the leading shoot, to encourage mounting which is the perfection of a forest tree. The stems all trees designed for timber, should be constantly, at timely attended to, as it is necessary to rub off buds, to cut off the side shoots, except here and there a small one, which may serve to detain the sap to the swelling of the trunk; but branches being left on of an strength, keep the tree from mounting, and draw crooked, and such branches, if cut off when large occasion knots, and sometimes a decay at the part.

Plantations, growing thick, should be thinned in time; but not too much at once, especially in hill situations; for as those trees which remain, come subdenly to be exposed, (after having been brought a under the shelter of others,) suffer much; getting crooked, stunted, and bushy, instead of having the desirable erect form, without which they are madapted for superior uses, or agreeable to the eye.

Ornamental trees, as the crab, black cherry, mountain ash, &c. may prove profitable, as well as agreeable here and there one amongst forest trees, and should therefore not be omitted: The wood is good.

## SECTION XI.

#### OF RURAL AND EXTENSIVE GARDENING.

RURAL and extensive gardening is naturally connected with a taste for planting forest trees; and in idea of the picturesque should ever accompany the work of planting. Merely for the sake of objects to ratify the eye, planting is very often pursued, and wherever trees can be introduced to improve a view rom the house, or accustomed walks, there a man, aving it in his power, as proprietor of the land, ought ertainly to plant.

If to planting in clumps, coppices, groves, avenues, and woods, be added levelling of ground, improving of vater courses, and pastures, making lawns, &c. the expence incurred would be honourable, and answered y pleasures of the sincerest kind! There are ways of bending money, that could be named, which are found nischievous in the extreme, and are therefore deevedly branded with disgrace; but he who distributes wealth into the hands of industry, working to useful surposes, and that delectable end of making the country bout him a garden, does it in wissom.

Yet here some caution may be necessary. "Do nohing too much," is a wise maxim. Building, plantng, and gardening, upon a large scale, have been ometimes attended with serious consequences, as when man's fortune has not been equal to the undertaking.

It were defirable to be able to perfuade to great thin

in this way; but prudence must guide.

Those who would do much in rural and extensi gardening, should not be forward to trust their ow taste altogether, though they may be ingenious. this business there is no making experiments, but a should be executed, as much as possible, upon ce There are professional men in this way, who peculiar practice, and appropriate talents, will enable rig of executing them, which would scarcely be projects by any private person. There is a variety of work and decorations in extensive gardening which injude cloufly introduced, might create a wasteful expense. This is an error that ought to be avoided, and mot probably would be, by those who have been in the habit of studying nature, and the powers of art, a hu her submissive handmaid.

Artificial decorations are at this time much less made use of than formerly, and the grandeur of past time in the way of gardening would now be thought trifling and mean. Witness sheard trees, statues, vales, water ble works, figured parterres, &c. in that style of garden ing, imitated from the Dutch, which has been long deemed a more hard for deemed a mere burlefque upon Nature, the grand cha

racteristics of which are ease and simplicity.

The pleasure we feek in laying out gardens, is now justly founded upon the principles of concealed art which appears like Nature; but still, whether ingenious contrivances and decorations, (altogether artificial) nious contrivances and decorations, (altogethere cial,) should be so entirely laid aside as they are, may deserve to be considered. Gardens were formerly and great improprieties were comloaded with statues, and great improprieties were committed in placing them, as Neptune, in a grove, and Vulcan at a fountain, large figures in small gardens, and small in large, &c. but, perhaps, works of the statuary might still be introduced, and the meeting with Flora, Ceres, or Pomona, &c. well executed, and

hing

ensa own

at a Ces whole nabl 11110

ecta vore ı judi ente

made

now art

nd in proper places, could hardly give offence. A errace as a boundary, is now feldom formed, but in ome fituations, such an eminence however might in everal respects be agreeable.

It would certainly be too much to attempt here paricular directions for extensive gardening. The pecuiar capabilities of any place must suggest what may
e done, and much judgment is necessary to plan
right. It is presumed only to give a few hints to hose private persons who would do something in this

hole private persons who would do something in this way, which they may consider as they please.

If trees are planted injudiciously, the error is a trifle; out if cut down so, the consequence is serious, and has sten been forely lamented; extirpation should therefore be well thought of before it is executed; especiore be well thought of before it is executed; especially trees about houses, for many dwellings have been that too hastily exposed, and deprived of a comfortable helter and shade. And why should a taste have premate ailed for so sudden a transferior and sailed for so sudden a transferior and sudden a transferior and sudden a transferior and sudden as transferior and railed for so fudden a transition, as no sooner out of the ouse than to arrive in the open country, or why should an extensive garden be thrown as much as polities hould an extensive garden be thrown as much as polities into a single view, when meeting with new obtained in our walks is so agreeable?

Hilly spots that are in view of the house should be characted with firs, as pleasant noble looking trees, and

ery hardy. Beech does well on high ground, espeially, if chalky. In low ground, not to mention alders

art and that tribe, the birch, and even the eak, should not ange e forgot, where the wet does not long stand.

About the house some shady walks ought always to About the house some shady walks ought always to may e provided, by thick planting, if not of trees, yet of overing shrubs, and evergreens, of which the laurel will be found the most useful. Here should be also a cood portion of grass plat, or lawn, which so delights be eye when neatly kept, also borders of shewy showers, the which if backed by any kind of sence, it should exist the hid with evergreens, or at least with deciduous and house, that the scene may be as much as possible vianted.

vacious. If there is good room, fingle trees of the far kind, at due distances, are admirable ornaments about a house, and clumps of shrubs all of the same kind

have a good effect.

Those who have much space of ground to decorate, do well to plant trees and shrubs of every kind, as enlarging the fources of amusement, and affording op portunities for observation; but if the allotment of ground for this purpose is contracted, then, of course those only should be planted, which by their neat for liage, natural fymmetry, and gay flowers, may be truly esteemed ornamental. They should be such a strike the eye of persons in general, though they have nothing of fingularity to engage the attention of the curious in plants. It too often happens, that good de forts of trees, shrubs, and flowers, are excluded for new ones, but if the latter are not more elegant, and generally pleasing, the practice is furely not a will one: in ornamental gardening, on a fmall scale, great care should be taken, in the choice of what is really pretty, that nothing dull or rambling be introduced.

In the most sheltered place, near the house, then should be an inclosure of a compact nature, as suppose of yew, dwarf elm, or hornheam (rather the former) open only to the South, as a necessary apartment to place things in from the greenhouse, or occasionally the hothouse, tender annuals, or any hard curious potted plants, for a summer residence. Spruit sirs answer very well, being kept clipt a little after Midsummer. For this purpose, or for hedges to separate, or divide, any spot of ground, the hop hornhead is better than the common sort, which holds its deal leaves on all the winter, and makes a litter at spring This business may also be easily effected by planting elder cuttings at a foot assumer, which will grow up

quickly, being kept moift.

The walks should always be wide, some (in general) serpentine, and contrived as much as possible upon a level

here fup. the part occaardy bruit afte fep2 bear dea

level

SECT. XI.

a level, as walking up and down hills can hardly be called pleasure. That they may be extensive, they hould fkirt the grounds, and feldom go across them. In small pleasure grounds the edges of the walks should be regularly planted with flowers, and long ones occa-fionally fo, or with the most dwarf shrubs; and neat heltered compartments of flowers, (every now and then to be met with) have a pretty effect. If the walks are extended to distant plantations of forest trees, every opportunity should be taken, to introduce something of the herbaceous flowery kind, which will prove the more pleafing, as found in unexpected fituations: The outer walk of pleasure grounds and plantations, should every now and then break into open views of the country, and to parts of the internal space, made pleasing, if not striking, by some work of art, or decoration of nature.

Water should only be introduced where it will run in full fight, and some fall of it should be contrived, (if possible,) for the sake of giving it motion and tound, because a lively scene of this element is always much more pleasant than a dead one. Every spring of water should be made the most of, and though fountains, &c. are out of fashion, something of this kind is agreeable enough. Near some piece of water, as a cool retreat, it is desirable that there should be something of the summer-house kind, and why not the simple rustic arbour, embowered with the woodbine, the sweethriar, the jasmine, and the rose. Pole arbours are tied well together with bark or ozier twigs.

"Before the design of a rural and extensive garden be put in execution, it ought to be considered, or an-(if possible,) for the fake of giving it motion and found,

be put in execution, it ought to be confidered, or annual dicipated, what it will be in twenty or thirty years time; for it often happens, that a delign which looks handfome when it is first planted, and in good proportion, becomes so small and ridiculous in process of time, that there is a necessity either to alter it, or destroy

G 2

destroy it entirely, and so plant it anew." This observation of Mr. Miller's, justifies the advice given of
employing the most skitful in planning and directing
pleasure grounds. To proportion the breadth of walks,
the size of carpets, casting and levelling of grounds,
parterres, &c. The disposal of fountains, statues,
vases, dials, and other decorations of magnificence to
most advantage, requires a particular address, says Mr.
Evelyn, or to speak more emphatically, a prophetic eye;
and though the taste is not now what it was in Mr.
Evelyn's time, yet, perhaps, the only difference is that
more skill is requisite.

What has been faid of the difficulty of rural and extensive gardening, is meant only as advice to proceed with cautious steps. The work is truly of the most worthy nature, and a taste for it deserves to be cherished. Mr. Shenstone, in an ode on rural elegance,

defends his favourite employment thus:

And oh! the transport, most ally'd to song, In some fair villa's peaceful bound, To catch soft hints from Nature's tongue, And bid Arcadia bloom around:

Whether we fringe the floping hill, Or fmoothe below the verdant mead

Or fmoothe below the verdant mead; Whether we break the falling rill,

Or through meandering mazes lead:
Or in the horrid bramble's room,

Bid careless groupes of roses bloom: Or let some shelter'd lake serene

Reflect flow'rs, woods, and spiers, and brighten all the

O fweet disposal of the rural hour!
O beauties never known to cloy!

While worth and genius haunt the favour'd bow'r And every gentle breast partakes the joy!

While Charity at eve surveys the swain, Enabled by these toils to cheer A train of helpless infants dear,

ion,

he 1

udgr. arde Speed whiftling home across the plain: Sees vagrant Luxury, her hand-maid grown,

For half her graceless deeds atone,

And hails the bounteous work, and ranks it with her own.

Why brand these pleasures with the name Of foft, unfocial toils, of indolence and shame? Search but the garden, or the wood, Let you admir'd carnation own,

Not all was meant for raiment, or for food, Not all for needful use alone;

There while the feeds of future blossoms dwell, Tis colour'd for the fight, perfum'd to please the smell.

Why knows the nightingale to fing? Why flows the pine's nectarious juice? Why shines with paint the linnet's wing? For sustenance alone? for use? For prefervation? Every fphere Shall bid fair Pleasure's rightful claim appear, And fure there feem of human kind, Some born to thun the folemn strife; Some for amusive talks defign'd, To foothe the certain ills of life; Grace its lone vales with many a budding role, New founts of blifs disclose,

Call forth refreshing shades, and decorate repose.

Mr. Shenftone succeeded admirably in laying out his grounds, and producing a delightful scene about the Leafowes. Several gentlemen have done great things n picturesque gardening, without the affiftance of proessional artists; but they have had a peculiar talent his way, improved by fludy and observation. Thus Mr. Walpole makes an easy affair of it, and says, the poffesfor, if he has any taste, is the best designer of his own grounds." And indeed, as they have ome fo frequently under his own eye and contemplaion, he must, in a great measure, be competent to he work; and at least, ought not to give up his adgment too implicitly to general undertakers of rural ardening.

Ornamental gardening depends much on the form of the ground, and therefore to shape that is the first object. Some situations may not need it, and, perhaps, a little alteration may produce a happy effect in others; therefore great alterations should not be attempted without manifest advantages, as either levelling, or raising ground, is a heavier business than is commonly

supposed, both as to time and expence.

Too much plane is to be guarded against, and when it abounds, the eye should be relieved, by clumps, or some other agreeable object. Hollows are not easily filled, and minences, mostly are advantageous, in the formation of picturesque scenes, in which the general principle of ornamental gardening consists. This idea has been pressed so far, that it is contended, a gardener should be a studier of landscape paintings. But without an immediate view to pictures, no doubt, grounds may be laid out in a way sufficiently picturesque. That view may be very agreeable in Nature, which would not be so in a picture, and vice versa.

Picturesque gardening is effected by a number of means, which a true rural genius, and the study of examples only can produce. These examples may be pictures, but the better instructions will be scenes in Nature; and the proper grouping of trees, according to their mode of growth, shades of green, and appear

ance in autumn will effect a great deal.

To plant picturefquely a knowledge of the characteristic differences of trees and shrubs, is evidently a
principal qualification. Some trees spread their branches
wide, others grow spiral, and some conical; some
have a close solitage, others an open one, and some
form regular, others irregular heads, the branches and
leaves of which may grow erect, level, or pendent.

The mode of growth in trees, as quick or flow, the time of leafing, and fhedding leaf, with the colour of the bark, are all circumstances of consideration in order

sto implicitly to general underta

to produce striking contrasts, and happy assemblages, in

the way of ornamental gardening.

mutually set off the beauties, and conceal the blemishes, of each other; to aim at no effects which depend on a nicety for their success, and which the soil, the exposure, or the season of the day, may destroy; to attend more to the groupes than to the individuals; and to consider the whole as a plantation, not as a collection of plants; are the best general rules which can be given

concerning them.

" In confidering the fubjects of gardening, ground and wood first present themselves; water is the next; which, though not absolutely necessary to a beautiful composition, yet occurs so often, and is so capital a feature, that it is always regretted when wanting; and no large place can be supposed, a little spot can hardly be imagined, in which it may not be agreeable. accommodates itself to every fituation, is the most interesting object in a landscape, and the happiest circumstance in a retired recess; captivates the eye at a diftance, invites approach, and is delightful when near: it refreshes an open exposure; it animates a shade. cheers the dreariness of a waste, and enriches the most crowded view. In form, in style, and in extent, it may be made equal to the greatest compositions, or adapted to the least: it may spread in a calm expanse to foothe the tranquillity of a spaceful scene; or hurrying along a devious courfe, add splendour to a gay, and extravagance to a romantic fituation. So various are the characters which water can assume, that there is scarcely an idea in which it may not concur, or an impression which it cannot enforce.

On the works of art in gardening, the following passage is pertinent:—" Art was carried to excess, when ground, wood, and water, were reduced to mathematical figure, and similarity and order were pre-

G4 ferred

ferred to freedom and variety. These mischiefs, how. ever, were occasioned, not by the use, but the pervertion of art; it excluded, instead of improving upon nature, and thereby destroyed the very end it was called in to promote. Architecture requires symmetry, the objects of nature freedom; and the properties of the one cannot, with justice, be transferred to the But if, by the term art, no more is meant than merely defign, the dispute is at an end; choice, arrangement, composition, improvement, and prefervation, are so many symptoms of art, which may occasionally appear in several parts of a garden, but ought to be displayed without reserve near the house: nothing there thould feem neglected: it is a fcene of the most cultivated nature: it ought to be enriched, it ought to be adorned; and defign may be avowed in the plan, and expence in the execution. Even regularity is not excluded: a capital structure may extend its influence beyond its walls; but this power should be exercifed only over its immediate appendages. of faultture are not, like buildings, objects familiar in scenes of cultivated nature; but vales, statues, and termini, are usual appendages to a confiderable edifice: as fuch, they may attend the manfion, and trespass a little upon the garden, provided they are not carried to far into it as to lose their connection with the ftructure."

### SECTION XII.

OF PRUNING.

#### I. OF WALL TREES.

IF this " mafter work of gardening," it has been faid, "that gentlemen prune too little, and gar-deners too much;" these extremes are to be avoided, as attended with peculiar evils, equalty mischievous: Wall-trees are presently spoiled by either practice. they are too full of wood, the shoots and fruits cannot be properly ripened, and if they are too thin, the consequence of the cutting that has made them so, is the production of wood, rather than fruit, forcing out shoots, where otherwise blossom buds would have been The defignation of trees to a wall necessarily occasions cutting, and on the skilful use of the knife much depends; but let not the ingenious young gardener be discouraged at the appearance of difficulty: a little study, practice, and perseverance, will clear the way, and if he does not become a complete pruner at once, he will in a reasonable time, and the work will prove one of the pleafantest amusements of a garden, not attended with fatigue.

Every one who has wall-trees cannot keep a professed gardener, nor is every one who calls himself so, qualified to prune properly. It is a great mortification to a man, who wishes to see his trees in order, not to

 $G_{5}$ 

be

be able to get an operator to attend them; let him refolve to learn the art *himfelf*, and the ability will be very gratifying to him.

Proud of his well-spread walls, he views his trees That meet (no barren interval between,) With pleasure more than ev'n their fruits afford, Which, save himself who trains them, none can feel.

COWPER.

As many words must be used on this article of pruning, for the sake of a little order, and the appearing less tedious, the business of managing wall-trees may be thus divided:—I. Concerning the FORM. 2. The HEALTH. 3. The FRUITFULNESS of them. A tree may be kept in good form, but be neither healthy nor fruitful, and may be both in good form and health, yet not fruitful; but if it is fruitful, it must possess both the former qualifications.

r. As to the FORM, or general appearances of the wall trees. If a tree is newly planted, the first thing is to head it down, by cutting off (if it is a nectarine, peach, or apricot) all the shoots, and the stem itself, down to a sew eyes, that the lower part of the wall may be surnished with new and strong wood. Make the cut sloping, and behind the tree, taking care (by placing the foot on the root, and the left hand on the stem) not to disturb the tree by the pull of the knise. Plaister the part with a bit of cow-dung, clay, or stiff earth.

The heading down is to be made so as to leave two or three eyes, or four, if a high wall, on each side of the stem, from which shoots will come properly placed for training. The number of eyes may be also according to the strength of the tree, and its roots. If there are not two well placed eyes on each side of the stem, two shoots, thus situated, may be lest, cutting them short to

two

two or three eyes each. Eyes, or shoots behind, or before, as being of no use, must be early displaced by rubbing, or cutting. This work is to be performed in spring, when the tree is putting forth shoots; i. e. about

the beginning of April.

If towards the end of May, there should be wanting shoots on either side the tree, having, perhaps, only one put forth where two were expected, that one shoot should be cut, or pinched down, to two or three eyes; and before summer is over there will be found good shoots from them, and thus a proper head be obtained. This work of shortening shoots of the year may be done any time before Midsummer; but in this case, all ill-placed, or superstuous growths, must be rubbed off as soon as seen, that those to be reserved may be the stronger.

As the lateral shoots grow, let them be timely nailed to the wall, close, strait, and equi-distant; but use no force while they are tender. If they are quite well placed, they will need no bending; but sometimes shoots must be laid in which are not perfectly so. Lay in as many good moderate sized shoots as may be throughout the summer, for choice at winter pruning, yet do not crowd the tree. As the shoots proceed in length, nail them to the wall, that no material daugling of them be

feen; but avoid using too many shreds.

In the formation of a tree, keep each fide as nearly as can be equal in wood, and the shoots inclining downwards, which is a mode of training necessary to fill the lower part of the wall, (none of which should be lost) and to check the toa free motion of the sap, which wall trees are liable to from their warm situation, and continual cutting. All the branches should have an horizontal tendency, though the upper cannot have it so much as the lower ones. Those that are perpendicular, or nearly so, mount the wall too sast, and run away with the food that should pass to the horizontals, which being impoverished by the vigorous middle branches, gradually.

fo

be

in

fa

di

bi

W

0

become too weak to extend themselves, and nourish the fruit. The pruner, therefore, must be content to have some of the wall, over the middle of the tree, unoccupied; or, at least, suffer none but weak, or very mode-

rate shoots, to find a place there.

The idea of a well-formed tree is formewhat reprefented by the ribs of a spread fan, or the fingers of the hand extended. Regularity is allowed to be so necesfary to the beauty of a wall tree, that some have even drawn lines for a guide to train by; but Nature, (ever free and easy) will not submit to so much formality, and fuch a perfect disposition of the branches are not necessary. A tree may be regular, without being linear, and the proper useful shoots are not to be facrificed to a fanciful precision. Though eroffing of branches is against rule, yet cases may happen (as in want of wood or fruit) where even this aukwardness may be per-The object is fruit, and to obtain this end, form must sometimes give place. "Barrenness being the greatest defect, crossing must not be scrupled, when barrennels cannot otherwise be avoided." A tree may be in fair fymmetry, and yet badly pruned; and thus some ignorantly, and others cunningly, put trees in order without a proper felection of branches, so that the best shall be cut out, and the worst left, merely because the latter fuits the form better, and gives a favourable appearance to the work as regular.

All fore-right and back thoots, and other useless wood; should be displaced in time, for they exhaust the strength of the tree to no purpose, and occasion a rude appearance. It is a very expeditious method to displace superstuous young shoots, by pushing, or breaking them off; but when they get woody, it is apt to tear the bark, and, in this case, the knife must be used: the better way is to dis-bud by subbing; yet a young survivant tree should be suffered to grow a little wild to spend the sap. There is one evil, however, attending on dis-budding, and rubbing off young fore rights, that

L

e

0

fome fruit spurs are thus lost; for apricets are apt to bear on little short shoots, of from half an inch to an inch, (or more) and there are peaches which do the same; so that it is a rule with some pruners to wait to distinguish spurs from shoots, and then to use the knife; but the less the knife is used in summer the better.

In regulating a tree, at any time, begin at the bottom and middle, and work the way orderly upward and outward. Never shorten in summer, (which would produce fresh shoots) except a forward shoot where wood may be wanting; but where the tree is really too thick, cut clean out what may be spared. None of the shoots produced after Midsummer should be nailed in, except where wood is wanting to fill a naked place: They never bear fruit.

The proper use of wails and shreds is necessary to the beauty of the tree, as well as a regular disposition of the branches; and in this business ingenuity will evidence

itself in neatness.

Mails that are weak and small can hardly be used, for they must be of sufficient strength to hold fast; but large nails do not look well, and hurt the wall more than smaller. There is, however, a fort made on purpose for this work, with slat heads, and robust shanks, called garden nails, and these are generally to be used; there is yet a smaller fort, with slat heads, that, in many cases, might do, and they have somewhat the advantage in neatrass. In default of these there are lath nails, of two or three sizes, that may be brought into use. It is proper to have two sizes, the larger for strong, and the smaller for weak shoots: trees trained to wood can hardly have rails too small.

Shreds thould be adapted to the strength of the branches, and the distance of the buds from each other; so that with strong shoots, having their buds wide, such broad shreds may be used, that would make weak shoots unlightly, and spoil them by covering the buds; many a well cut tree has been made disgutting,

merely by irregular and dangling shreds. An uniformity of colour can hardly be accomplished, but a regularity of size may; scarlet, if all alike, look best; and white the worst. The general width of shreds should be from half an inch to three quarters, and the length two inches to three, having some wider, longer, and stronger, for large branches. In the disposition of shreds, some must have their ends turned downwards, and some upwards, as best suits, for bringing the shoots to their proper place, and strait direction. Though some pruners observe a sort of alternate order, yet the ends hanging chiesly down, (if it may be) will be found to look best. Use no more shreds and nails than necessary to make good work, as the effect is both rude and injurious.

The hammer used in nailing branches should be near and light, with a persectly smooth and level face, about two thirds of an inch diameter, having a claw for drawing nails. As nails are apt to break out pieces of the wall in drawing, it is a good way to give the nail a tap to drive it a little, which loosening it from its rust, makes it come out easier, and so saves a wall from large holes, which is a material thing, as they harbour insects

and filth.

Trellifes have been recommended to be placed against walls, as a means of keeping a wall found, and giving the fruit more room to swell. In the training of fruit trees that do not require the greatest degree of sun, and in situations where the loss of a little heat is not material, this method of training trees is a good one. But, perhaps, there are not many situations in England, (common as it is on the continent) where this mode of culture can be adopted; as all the sun we meet with here, is generally but barely sufficient for peaches, nectarines, grapes, and sigs. Apricots, however, may do, and when trained upon a trellis, in a southern aspect, grow fines, and are less mealy than directly against a wall.

Trellises should be made of seasoned deal, and squared to slips of three-sourths of an inch, or a trisle wider; and fixed close to the wall, so as to form upright oblongs of twelve inches by six. In this way of training, the shreds ought to be finer, and the nails much smaller; but the branches may be tied with bass, &c. if the trellists set a little from the wall, as suppose an inch.

It may be observed, that tying saves the expence of nails and shreds, close set buds are never covered, and damage from the hammer is avoided. By trellising, a tree will be less infested with vermin and insects, which breed in the holes made by nailing. In this mode of training, the fruit swells freely, grows larger, and is of more equal flavour; so that it deserves trial where it is

likely to fucceed by fine fituations.

Let the young gardener be advised resolutely to observe the pruning laws, and keep all in perpetual order, for his trees will run presently to consusion and ruin, if.

mattention and neglect take place.

2. The HEALTH of wall trees is greatly provided for, by observing the directions already given, concerning their form; for if observed, each shoot will have the proper benefit of sun and air, to concoct its juices,

and prepare it for fruiting.

It injures a tender shoot when it presses hard against a nail. If the hammer strikes a shoot, and bruises the bark, it often spoils, if not kills it, by the part cankering. The shreds may be too tight, so that the shoot cannot properly swell; and if shreds are too broad, and too numerous, they are apt to occasion sickness, and prove a harbour for insects and filth: Let the number be lessened at all opportunities. A slip of the knife may wound a neighbouring branch, and make it gum, canker, or die. It will require care, and some practice, to avoid this accident; and in order to it, keep the point of the knife sharp, and mind the position of it when cutting.

cutting. Cut close and floping behind the eye; neith so near as to injure it, nor so wide as to leave a stub.

Digging deep with a tpage about notices he ground raining the roots, and keeps them too low in the ground raining the roots, and keeps them too low in the ground raining the roots, and was a supplied to run higher; and a way when they should be encouraged to run higher; and a nothing but well confumed dung, or other manure the drops freely, should be used about fruit trees, it is a good way to dig, or fir the ground carefully with an afpara gus fork. Wounds and bruises hurt roots, as much a branches, and though cutting small roots asunder by branches, and though cutting fmall roots afunder by a franches, does good rather than harm, yet large ones an en often much injured by this instrument.

The extremities of a tree will not be in vigour with out a first attention to the middle, that it have no ftrong lie wood, growing erectly: this was before directed, and must be observed. When the fides of a tree are well seld extended, and full of healthy wood, then forme shoots of moderate substance may be trained up the middle.

The bending of a branch much is a violence to be and avoided; fo that every shoot should be kept from the first in the direction it is to grow.

Luxuriant wood must be particularly attended to, to get rid of it in time, before it has robbed the weaker all branches too much. That is buxuriant wood, which, according to the general habit of the tree, is much larger reathan the rest; for a shoot that is deemed luxuriant and in one tree, may not be so in another. If strong cut wood, that is not very luxuriant, happens to be a the bottom of the tree, so that it can be trained quite be horizontally, it may often be used to good purpose, as bet this position checks the sap. A luxuriant shoot may be to kept in fummer where it is not defigned to retain it ing merely to cut it down at winter pruning to two or three he eyes, for getting wood where wanted the next year; no or this shortening may take place in June, to have new shoots the present year. Luxuriant shoots may be sometimes retained for a time, merely as waste pipes. More ec . XI

fore concerning luxuriant wood will be found in what ollows.

All difeafed, damaged, very weak, or worn out and vay for better; but if a tree is generally diseased, to make one caution must be used not to cut out too much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if the caution much at a good noce, if there is any hope of reflective in the caution much at a good noce, if the caution much at a good noce, if the caution much at a good noce, if the caution much at a good noce is a good noce in the caution much at a good ranches (as they occur) should be cut out, to make great deal; but prune it so as to have a grant deal; but prune it so as to have a grant ling of the best of the branches, and keep short of an eve or two, of the weaker ones; in a sort es an engths of an eye or two, of the weaker ones; in a fort

Young trees are very apt to decline, and sometimes with Young trees are very apt to decline, and sometimes trong lie, if suffered to overbear themselves the first year or wo of fruiting: The remedy is obvious, and should well esolutely be applied.

A weak tree is helped much by training it more

to be and so the shoots are more likely to swell: such a tree the should be kept thin of branches, and always pruned arly in autumn, keeping the top free from such wood o, to s is stronger than that which is in general below, and taker ill shorter than usual.

Old decaying trees should be lessened a little every

right rear, and constantly watched, to observe where young right rear, and constantly watched, to observe where young that and strong shoots are putting out below, in order to took to them; and though the time for doing this is a commonly at autumn or winter pruning, yet it may be best done in summer, as the shoots would thrive the bester, observing to put some graffing clay, or cow dung, to the part, to prevent gumming, which summer pruning is apt to occasion. A judicious pruner may bring the oldest, and most ill-conditioned tree, to a healthy that bearing state, if all is but right at the root, it having have a good soil about it.

Keep all wall trees clean, and particularly weak ones, from moss, cobwebs, or other filth; and attend to interest, snails, caterpillars, and smother sies. Any bark

ore lects, fnails, caterpillars, and smother flies. Any bark

that is decayed by cracks, &c. must be cleared awar to the quick, either by rubbing, or the knife, as sild and insects are apt particularly to gather there: wine

the part clean.

Confider the foil about an unthrifty tree, and if it is thought bad, improve it by moving away as much of the old as conveniently can be done. The roots may be laid quite bare, and examined, in order to cut off decayed or cankered parts, and to apply immediately to them fome fine and good fresh earth, with a little the rough rotten dung in it, and a sprinkling of soot, or wood ashes.

Hog dung, applied fresh, is said to have a peculiar efficacy in recovering weak trees; and cow dung may reasonably be expected to do good, if the soil is a warm or hungry one, and if not so, the hog dung is not a proper, as it is a cold dressing. If the soil is a strong one, a compost of sowls, or sheep's dung, lime, with any fresh light earth, one part of each of the former, and three of the latter, mixed with the soil that is taken of will be a proper manure; to which a little sharp same may be added. An animal dressing, as of entrails, any carrion, or bullock's blood, applied to the roots, has been frequently found effectual to make fruitful, and to recover decaying trees, and in particular vines. At these applications should be made late in autumn, a early in spring.

The constitution of a tree is sometimes naturally barren; or the soil that the roots have got into may be nought and deleterious, that no pains, or perseverance will avail any thing; but growing worse and work admonishes the owner to take it up, and try another plant, rectifying the soil thoroughly, if the evil it thought to arise there. The smother sty does sometime repeatedly attack the same tree, which is a sign of inherent weakness, for the juices of a sickly tree are sweets than those of a sound one, and so more liable to such attacks. Sometimes a tree of this kind, when remove

OVE

o a good foil, and pruned greatly down, does very well. A foil too rich of dung often occasions trees to be blighted, and the remedy is to impoverish it with a sharp and.

In order to health and strength, a tree must not be kept too full during fummer, as it prevents the proper may ripening of the wood, and makes the shoots long jointed. If de If more than one shoot proceed from the same eye, rely to serve only the strongest and best situated. A crouded the tree cannot be healthy, and it becomes both lodging and food for infects. The bloffom buds of a tree being formed the year before, will be few and weak in a thicket of leaves, as debarred of the necessary sun and air: But in order to avoid an over-fulness, do not make any great amputations in fummer, lest the tree should gum.

In clearing a tree of superabundant wood, take care not to cut off the leading shoot of a branch. All shoots after Midsummer should be displaced as they arise, except where wanted to fill up a vacancy. In a too vigorous tree, the Midfummer shoots may be lest for a while on those branches that are to be cut out at winter pruning, as cutting fuch trees in fummer is to be avoided as much as possible; so that a little rudeness in a luxuriant tree may be permitted as a necessary evil, provided it becomes not too shady, or unfightly. Watering wall trees with an engine on a fummer's evening, is conducive to their

health, and frees them from infects.

The subject of blights is too copious, difficult, and uncertain, to be entered upon here farther than has been.

3. The FRUITFULNESS of wall trees, (the ultimate object of planting and training them) comes now to be spoken of. Their proper form and health being good, the foundation is laid, but several things are yet to be done to obtain the end proposed, and this chiefly regards

regards the principal cutting, or what is called winter

If trees have been planted far enough asunder, it is a happy circumstance, as the proper borizontal form, and the open middle, may be preserved. The longer the horizontals are, the more necessary it is to be careful to suffer none but weak branches in the center uprightly. If trees are confined as to length of wall, they of course take a more erect form: but still strong wood should not mount just in the middle.

If the trees have been properly attended to during funmer, there will be now (at their principal, or winter pruning) the less to do; and the leading objects are, to thin and to furnish them, or, in other words, to take out what is to spare, and to cut what is lest, so as to fill the tree properly again by succeeding shoots.

A tree is to be thinned of damaged, unpromising, and ill-placed shoots, and of woody branches that are decaying, or reach far without fruitful shoots on them, and always fome of the old wood should be cut out, where there is young to follow, or supply its place. Of the fair and well placed shoots also, the superabundance is to be taken away, so as generally to leave the good ones at four, five, or six inches asunder, according to the size of the wood and fruit.

Luxuriant wood, i. e. those shoots that are gigantic must be taken out from the rest, as they would impove rish the good, and destroy the weak branches, and are never fruitful; but if a tree is generally luxuriant, it must be borne with, and the less it is cut, comparatively speaking, the better. Such a tree, after a sew years, may come to bear well; and when it begins to shoot moderately, some of the biggest wood may be taken out each year, or shortened down to two or three eyes, and so brought into order. The more horizontally free shooting trees are trained the better, as the bending of the shoots checks the sap. A strong shoot or

NO,

o, of a very luxuriant tree, may be trained perpenular for a time, to keep the horizontals the more oderate.

As the pruner is to begin below, and towards the m, so the object in thinning must be, to prefer and to we those shoots that are placed lowest on the branches, at so the tree may be furnished towards the center. It is that those left are sound, and not weak, or over ong, for the moderate shoots generally bear best. Teak shoots are always more fruitful than strong ones; if it is difficult they are furnished with fair blossoms, should be st where a tree is full of wood, and even preferred to oderate ones, on a very flourishing tree.

In this thinning business, the young pruner must be ment to go on deliberately, that he may consider well fore the knife is applied. To make a proper choice the great point. After hesitating, to be sometimes at loss, must not discourage a learner, for good pruners ten are, and no two adepts would choose just the

me shoots.

The next object is to furnish a tree. In order to is, the thinning of old wood, young being ready (or fily to be procured) to follow, has already been menned; but the principal step is the shortening of the bots, which occasions them to throw out below the t, for future use. If they were not to be shortened, e tree would presently extend a great way, bearing is lifty at the extremities, and all over the middle it buld be thin of fruit, and thus a great part of the wall it; which not to suffer, is one of the arts of a pruner at shews his skill.

The mode of bearing in peaches, nectarines, and aprits, is on the last year's wood, which makes it necesy to shorten, in order to a certain supply of shoots for aring the next year; and thus to have succession wood

every part of the tree.

The rule for shortening is this: Consider the strength the tree, and the more vigorous the shoots are, cut

off the less. If a luxuriant tree were to have its shoot much shortened, it would throw out nothing but wood and if a weak tree were not pretty much cut, it would not have strength to bear. From vigorous shoots one fourth may be cut off; from middling ones, one-think

and from weak ones, one-half.

In shortening, make the cut at a leading shoot but which is known by having a bloffom bud on the fider it, or, which is better, one on each fide. Bloffom but are rounder and fuller than leaf buds, and are difcen ible even at the fall of the leaf, and plainly feen earl in the fpring. It is defirable to make the cut at tui blossoms, yet as this cannot always be done, the de proportion of length must generally determine. It ofto happens, that the bloffom buds are chiefly, and fom times all, at the end of the shoot; but still it should shortened, if it is at all long. Never cut where the is only a bloffom bud, and prefer those shoots that a shortest jointed, and have the blossoms most in the mi dle. The shoots that lie well, and are fruitful, a healthy, and but a few inches long, may be left while Always contrive to have a good leader at the end every principal branch.

Young trees (as of the first year of branching) should have the lower shoots left longer in proportion, and the upper shorter, in order to form the tree better to the filling of the wall: the lower shoots may have three to

four eyes more than the upper.

In furnishing a tree, consider where it wants woo and cut the nearest unbearing branch (or if necessary a bearing one), down to one, two, or more eyes, according to the number of shoots desired, for in such closs shortening, a shoot will come from each eye. With view to wood for filling up a naked place, a shortened after Midsummer may be thus shortened; though the general rule is, to displace all such late shoots useless; the dependence for blossoms being on the earl formed shoots.

Th

The time for the principal, or winter pruning, is by me gardeners held indifferent, if the weather is mild the time; but a moderate winter's day is often quickly llowed by a severe frost, which may hurt the eye hird ad bloffom next the cut. The best time is at the fall the leaf, and may take place as foon as the leaves gin to fall. November is, generally speaking, a good idea me, and if this month is past, then February, if it is ild, or as soon after as possible, for when the blossom idea get swelled, they are apt to be knocked off by a state touch or jar early ttle touch, or jar.

An autumn pruning will make the tree stronger, and the blossoms come bolder and forwarder; and if trees ofte the then cut, as it lessens the work of spring much, sis alone is a good argument for it. This practice ives also a better opportunity to crop the borders the moderately) with cauliflowers, lettuces, radishes, &c. fland the winter. Pruners in general, however, like spring cutting, because they then see the blossoms lainly, and thus more readily make their election of moots. Yet if the first fine weather and leisure were mbraced in autumn, it were certainly better; and urely it must give satisfaction to see the trees in order

ll the winter. But though an autumn pruning is to be earnestly ecommended, it were best to leave young trees, for a ear or two, after heading down till spring; and luxuiant trees ought certainly to be fo left, not only to theck the strength of the coming shoots, but to see beter where their blossoms are, that no fruit be lost, as

when in this state they bear but idly.

In an autumn pruning, apricots should be cut last;
but if spring be the time, the rule is to begin with pricots, then peaches, and then nectarines. Apricots hould not be so much shortened as peaches, nor do they o well endure the knife. Shoots of the apricot, if uner a foot, may be left uncut, if there is room. The purs of apricots should be spared, if not too long, or

or off.

old

or f

ny

A

ng ff l

icu o fi

es,

ent

R

numerous, for they bear well, and continue for year Some forts of peaches are also apt to put out fruit four

and must be managed accordingly.

If much alteration is to be made in a wall tree, i will be necessary to un-nail a great part, if not the whole tree, or a fide of it, at least. When a tree h filled its space, something of this fort must be done, a the worst, oldest, largest, and most unprofitable wo taken out. If good fruitful wood be cut away to n duce the tree, then that is to be referved which wil lay in straitest and in the best form, branching out the nearest towards the stem.

Thus having finished the directions for pruning apriests, peaches, and nectarines, a few short observa tions may be made, and fomething faid concerning the management of those wall trees, in order to obtain goo

After trees have been pruned, it will be proper to look them over, to see what can be amended, as the will hardly be done perfectly at first; this business may lip, be let alone till blossoming time, and then some judicion we alterations may perhaps be made, (with care) as taking ob out fome weak, or other shoots, that prove barren, and may be spared, or cutting some down to the knit-fruit ully both to benefit that, and make room for the new wood April will be the time for this.

The pruner's business is not simply in providing present, or a next year's crop of fruit, but to manage his trees so as to lay a foundation for years to come He is to anticipate consequences, and provide for the arm

future.

Particular as the directions here given for pruning erh have been, they cannot have comprehended every printed and experience will readily and fible case, but good sense and experience will readily fupply what may be wanting, if the inftructions affords

Those who bire a workman to perform their pruning thould have three fummer operations besides the winter, he t

i. e.

e. in May, July, and September, earlier or later in hese months as the season is, taking care to be satisfied of the skill of the performer.

To preserve blossoms from inclement weather, is a hing some persons are curious in, though on the whole, hey may be (as they generally are) left to take their hance. After expence and trouble, this business is ften done to no purpole, or a bad one. The covers work is done irregularly, as perhaps covered too close or a time, and then left uncovered, they are sooner cut off.

Many contrivances for shelters have been used. The or fern, (which is best when dry) is as little trouble as my; but they should be fixed carefully, so as not to lip, or be moved by wind, and not so thick as to shade wermuch. A slight covering is of service, and rather vermuch. A flight covering is of service, and rather o be recommended than a thick one.

Nothing more than an old net has been used success-fruit ally by some gardeners for the purpose.

A coping projecting from six inches to a soot, accordng to the height of the wall, is serviceable, as keeping of heavy rains, and also frosts, whose action is perpenicular: This coping, when it is of thatch, though not omes of fightly, is best: But perpetual covers, if wide, do in the same by keeping off dew and gentle rains.

The best covering for the protection of blossoms is,

erhaps, that which Mr. Miller recommends, "made with two leaves of flit-deal, joined over each other, addit and painted, fixed upon the top of the wall with pullorde es, to draw up and down at pleasure, forming a fort of enthouse."

ning Reed or fraw hurdles have been used to place before inter; he trees in severe weather; and if only set at right

lo

alk

en

angles against the wall, towards the east, when the wind is strong from that quarter, they do good: a long tree might have one let up against the middle of it, a well as at the east end. Hurdles, covered with a mat, or cloth over them, do very well; and if too short to reach the top of the wall, they may be fet upon forked stakes fast in the ground.

Poles fixed in the ground to the height of the wall, at small distances, and fix inches from it, might be co-

vered with mats.

Whatever covering is used, it should be left no longer on than necessary, and it should be well secured from flipping or rubbing against the tree by wind. It should not be used till the blossoms get a little forward, not continued longer than while the fruit is well fet, being regularly put up at night, and taken off in the day, except in very bad weather: Trees covered too long get fickly.

The thinning of fruit, when too thick upon the treat is a matter that must be attended to, for it will eventually prove lofs, and not gain, to leave too many for ripening. It weakens the tree, prevents the knitting of fo many, or fo strong blossoms for the next year as are defirable, and hinders the fruit from coming to is fize and flavour. Do this work when the fruit is

about the fize of a horse-bean.

The rule for thinning should be, to leave no two fruits fo close as to swell one against another; except indeed the tree is generally short of fruit, when twins may be left on ftrong branches. Three or four, on a long and strong branch, are quite enow, and so in proportion for weaker wood: this is faid of the larger forts of peaches and nectarines; apricots may, in general, be left fomewhat thicker on a flourishing tree, and the leffer kinds of peaches and apricots may still be somewhat more numerous, as the early masculine apricot, the nutmeg peach, and nutmeg nectarine: there may be more nectarines left on a tree than peaches.

As

As the apricots gathered to thin a tree are used for ones, so are sometimes the nectarines, but let not too many of either grow for this use, or stay too long on the tree before they are gathered. Thin the more freely sourishing young trees, (to the third year) and weak old ones. Trees should be thinned by cutting off the fruit with a sharp pointed knife, and not by pulling, which may tear the bark, and, if joined (as in clusters) to another fruit, the pulling off one, often damages the soot stalk of the other, and occasions its dropping.

As to thinning the leaves of wall trees, too much iberty should not be taken, though in some measure it may be necessary to give colour and ripeness to the ruit. Thinning away a few leaves, where thick, is erviceable to ripening the wood to form blossoms. When leaves are greatly multiplied, and shade the fruit nuch, a few at a time may be displaced, if the fruit is learly full grown, but rather by pinching or cutting the leaves, just above the foot stalk, than by pulling.

In gathering wall fruit, do not pinch it to try if it is ipe, but give it a gentle lift, and if fit for eating, it will readily part from the foot stalk. Those peaches and nectarines that drop by their ripeness are yet good some say best) for the table; but apricots have a marter and more agreeable flavour before they are thoughly ripe.

As to the dropping of fruit, when it has attained to ome little fize, in very light foils, it may be owing to rought, use watering therefore deep and wide. But he cause seems often to be some injury from insects, throsh, that the embryo fruit has suffered at the soot alk, which can only sustain its burden for a while, and ten its own weight breaks it off. See p. 51.

warm foil, and full fun, or some accidental advantage, as being planted at the back of a warm chimney; and though they will grow and bear leaves any where, they will not fruit well in *England*, without a favourable season, or hot summer.

for two or three years, that they may get strong. If the plant has a weak root, not above one shoot ought to grow the first year, which should be cut down in au-

tumn to two or three eyes.

The best time for the principal, or winter pruning of vines, is best as soon as the fruit is off, or the leaves falling. November does very well, and if this month passes, February should be adopted, rather than quite in the winter. Late in the spring they are apt to bled

by cutting, which greatly weakens them.

The mode of bearing in vines is only on shoots of the present year, proceeding from year old wood. The rule, therefore, at winter pruning is, to reserve such shoots of the year that are best situated as to room, for training of those shoots that are to come from them, which will be almost one from every eye. Make choice of those that are placed most towards the middle, of stem of the vine, that all the wall may be covered with bearing wood; and every year cut some old wood out that reaches far, to make room for younger to follow.

The form that a vine takes on the wall is various and not very material, whether it be more horizontal or perpendicular. The form must-be governed according to the space of walling allotted to it; sometimes has ample room, as at the gable end of a house, and sometimes it is confined to a low wall, or between trees windows, &c. The reserved shoots should be twelved or fifteen inches as funder, if they are strong, and we ones may be something less: hardly too much room

The *shortening* of the shoots should be according to their strength and the space there is for training the

hoots that will be produced, which always grow very ong. If there is room, three, four, or five eyes may e left, but not more to any shoot, except it is desirable o extend some shoot to a distance to fill up a particular pace, and then eight or nine eyes may be left, which being repeated again another year, and fo on, a vine will foon reach far.

Sometimes vines are trained on low walls by a long extended horizontal branch, a few inches from the ground, as a mother bearer. Those shoots that come rom this horizontal are to be trained perpendicularly, and cut down to one or two eyes every year, that they may not encroach too fast on the space above them, If the vine is confined to a narrow but lofty space, it is to be trained to an extended perpendicular mother bearer, having short lateral shoots pruned down to a single eye, or at most two. The management of vines requires severe cutting, that they may not be too full in the summer, for they put out a great deal of wood, and extend their shoo s to a great length; and therefore the young pruner must resolve to cut out enough.

An alternate mode of pruning vines is practiced by some, one shoot short, and another long; i. e. one with two eyes, and another, with four or five. Severe cutting does not hurt vines, and make them unfruitful, as it does other trees; and therefore, where short of room, they may be pruned down to a fingle bud, as the case

requires.

The fummer management of vines must be carefully attended to. As foon as the young shoots can be nailed to the wall, let them not be neglected; but remember they are very tender, and will not bear much bending: train in only the well-placed shoots, rubbing or breaking off the others. The embryo fruit is soon seen in the bosom of the shoot, and those thus furnished are of course to be laid in, as many as can be found room for, in preference to those shoots that are barren, which nevertheless should also be trained, if they are strong and

well placed, and there is space for them. Rub off all shoots from old wood, except any tolerable one that proceeds from a part where wood is wanting to fill up some vacant space. If two shoots proceed from one eye displace the weakest, or the outermost, if they are both alike, and the fruit should not direct otherwise. Vina grow rapidly, and must be nailed to the wall, from time to time, as they proceed, that there may be no rude dangling, which would not only have a slovenly appearance, but in several respects be injurious.

The flopping of the shoots is to take place, both as to time and mensure, according to the strength and situation of them, or whether fruitful or barren. Those weak shoots that have fruit, and are rather ill placed, or confined for room, may be flopped at the fecond, or even first joint above the fruit, early in the fummer; but those shoots that are flring, and have from to grow, should not be stopped till they are in slower, (in July) and at the third or fourth joint above the fruit. fhortening the fhoots of the vine, do it about half an inch above an eye, floping behind a plump and found The barren shoots are to be trained at full length, and not flopped at all, if there is room for them, or, at least, but a little shortened towards autumn, as in August, because they would put out a number of ufeless and strong side-shoots, if cut before.

The side-shoots, i. e. those little ones put out by the eyes that are formed for next year, are commonly directed to be immediately displaced by rubbing off, as soon as they appear; and if the vine is large, and the shoots slender, it is very proper; but if otherwise, their being left to grow awhile (so as not to get too rude and crowding) is rather an advantage, in detaining the sap from pushing the shoots out immoderately long; and when these are taken off, the lower eye of each may be left with the same view. But the side shoot, that proceeds from the top of each shortened branch, should be

In order to fruitfulness, vines will need dreffing with time fort of manure, for though they grow in vineyard countries on rocky hills, and in very shallow soils, and have done so on some chalky, not, gravelly hills in England, yet some warm spirituous food they must generally have applied, or they will produce little good fruit.

Some people are very fond of exposing the fruit of the vine to the full fun, by stripping off leaves; but this should not be practiced till the bunches have attained their proper size, needing only to be ripened, and even then but little should be done in this way: The loss of

leaves is an injury to every plant.

. . . . . .

Fig trees are best pruned early in October, (cutting the leaves off) but the more usual time is early in spring, as after an autumn cutting (if late) they are apt to die down; but if not completely pruned at this time, let, at least, stragglers be taken out, and the rest laid in close without straining: Thus they will be more conveniently covered.

The mode of bearing in the fig is, that fruit chiefly comes the present year on the little shoots from wood of the preceding, and that towards the ends of the branches; which circumstances dictate the rules for pruning: Two years old wood will bear some, but

older wood never.

The shoots, during summer, are to be laid in at full length, plentifully, as room will permit. The weak, ill placed, or superabundant ones, cut clean out; yet father break, or sub them off, in an early state of growth, for cutting branches or shoots in summer is apt to make them bleed, as it is called; i.e. the sap run; when cut in autumn, the sig will sometimes bleed for a day

day or so, but if late cut in spring, the oozing will con

tinue perhaps a week.

At the principal pruning, the strongest and the closed jointed shoots are to be preferred, and lest about seven or eight inches asunder, without shortening. Let the spare shoots be cut out close and smooth, and as much of the old wood as may be; for the tree will increase too sast, and get too naked of bearing wood in the middle, if this is not freely done; and the essential point in the management of sig trees is, (as indeed of all wall trees) to have young wood all over it, and particularly in the middle, and towards the bottom. Wood is seldom wanted in a sig tree, but where it is, the shortening of a shoot, properly situated, (by taking off the leading bud, or cutting lower, as the case requires) is sure to produce it: Do this in April, as the best time.

When hard frosts are expected, strew some ashes, and some litter over them, on the roots of fig trees. Mats should be nailed over their branches, (first pulling off the figs) as the succulent nature of their wood makes them tender. These coverings are to remain till the frosts are judged to be over, and then let them be covered up at night, and not by day, for a week or two,

to harden them by degrees.

But fig trees will mostly survive hard winters, when in standards, without covering; and though shoots trained to a wall are tenderer, yet peasebaulm hung close among the branches (at the approach of sharp frosts) will preserve them. This fort of protection, as affording plenty of air, is by many good gardeners preserred to the more common practice of matting. But if mats were contrived to roll up and down, or kept a little distance from the tree, so as to give more or less air, as the weather is, the health and fruitfulness of the tree would be better insured, for too close (and as it commonly happens in consequence too long) covering is injurious to both. Fig trees that have been close covered are often hurt by

in early uncovering, and yet the spring air, as soon as

offible, is defirable.

It is worthy confideration and trial, whether fig rees, against a good wall, would not do best on a trellis, as thus, if they have fufficient heat, they would not be forced into wood, which they are apt to have too much of. In this way they might be protected in winter, by tucking in branches of evergreens, fern, &c.

PEARS come next under our confideration, as a few

of the best forts are a good wall fruit.

A young pear tree, being planted against a wall in. autumn, should not be cut down till fpring, when the head is to be reduced according to the goodness of the: root, and fo as to lay a proper foundation for covering the wall. If it has a bad root, all the shoots should come off, and only the stem be left; with a few eyes to form new shoots, as was directed for peaches, &c. But generally some of the shoots are to be left, with due thortening, only taking it as a rule, that it is not proper to leave much wood on; but to prune down freely, in order to the putting out strong shoots for parent branches. See heading down, under the directions for espalier pruning.

The form of pear trees is to be governed by the If the space allowed the tree is low and long, it must of course be trained perfectly horizontal; but if there is room above, and a deficiency of length, the form becomes more erect: Yet even in this cale, the lower and more horizontal branches should be allowed to get the start a year or two, before the middle is permitted to fill, which ought not to have any over frong wood, left it run away with the strength of the tree, . and keep the extremities weak. Train the brunches at length, without shortening, and keep them at from fix to eight inches diffance, according to the fize of the

H 5 fruit ; .

is

ir

k

f

į

t

2

1

t

4

fruit; remembering it is effential, that the branches be clear of one another, for the sun and air to have free access: Pruners should consider this circumstance, in all trees, more than they generally do. The reason for not shortening the branches is, that wood is always thrown out from two or three eyes below a cut, and so the tree would become a thicket of useless wood, if

fuch cutting took place.

The mode of bearing in pear trees is on short spurs, which appear first towards the ends, and then form themselves all along the branches, which do not produce blossoms for three or four years from planting, and sometimes (according to the sort, or perhaps soil) for several years more. When they are come to fruiting, some pears bear pretty much on year old wood, some on two, others on three. The same branches continue to bear on spurs from year to year, and most when sive or six years old; but as in course of time the branches may become diseased and barren, and not produce so since fruit as younger wood, it is always proper to procure a succession of young bearers, as the opportunity of good shoots offer, cutting out old wood.

As to projecting wood, most gardeners allow of it in wall pear trees, though some not. The wood should not, however, be suffered to project above three or four inches; and though there are bloffoms at the ends of year old wood, yet they should be either cut clean out, or down to an eye or two, for forming fruit spurs, 25 they will often do; though they are more apt to produce These shoots being cut down again, only wood shoots. tufts of wood are thus produced, which makes a tree appear ragged; fo that whether it is best to cut all spare shoots clean out, or to cut (some of them at least) down to little stubs, or false spurs, is hardly yet determined: The advocates for both practices, however, speak very positively for their way. The cutting clean out is much the neater, and less troublesome way, and is therefore best, if as much fruit is to be obtained

by it: It has been faid more may be; but I have not

feen it proved.

The occasional pruning of pear trees during summer is necessary, less the strength of the tree be spent in vain, the fruit robbed and shaded, and the extremities impoverished. Whether all the shoots that are clearly known to be wood shoots (from their length) should be cut out during summer, is a question, but proceed as follows:

Where fruit sours are wanted, the moderate wood shoots may be left to grow to some length, till the wood is hardened, and then broke off to about six inches, which, being left to the winter pruning, may be cut down to one eye, with the hope of getting a sour there. But eyen fair source should not be suffered to grow too thick: trees bearing small pears may have

theirs four inches afunder, and the large fix.

Several fummer shoots will come out about the fruit spurs; yet it is not advisable to cut all of them off as they appear, but only the strong and most unsightly: one moderate shoot may be left to each, and shortened when the wood is hardened, to about six inches, and cut clean out at the general pruning: All supersuous shoots, except those mentioned as allowed of, should be displaced while young; but though rubbing, or breaking off, in all cases are preferable to the knife, do not use this method when shoots are so big as to tear the wood with them. Shoots from spurs will never come to any thing, and must not be trained.

The time for general or winter pruning of pear trees ought to be November, as the blossoms are then very discernible, and at spring pruning they get so turgid and tender, that almost the least touch knocks them off, or even the jarring of the tree. What is now to be cut out will be understood from what has been said; only when the bunches of spurs get too thick and projecting, some must occasionally be removed, and a thin sharp chissel and mallet will do the work well,

H 6 when

ft

th

where the wood is too strong or awkwardly placed for the knife. When a tree gets to the extent of its bounds, it is to be shortened down to a well-placed young shoot, which may serve for a leader; which leader should be already provided by a provident selection in the summer.

Where wood is wanted to fill a vacant place, a shoot may be accordingly shortened; but otherwise there must be no shortening, except down to a single eye, with a view (as was said) to forming fruit spurs, where the tree is thin of them. And when wood is desired in any particular part, where there is no shoot to cut down for the purpose, a notch crosswise (somewhat long), will generally produce it, and the more certainly, if made just above a joint, or knot. Such notching of pear trees does no harm, but rather good; as many choose to do it freely, in order to check their too great aptness to luxuriancy.

The thinning of the fruit on pear trees is frequently necessary. They put forth numerous blossoms, and many of them fall, and even the fruit will do so when it is set; but as soon as it is promising (by the healthy shining appearance of the skin) that the fruit will hang, thinning to one pear on a spur, will improve the fruit lest, and help the tree: this work do with a small sharp pointed knife.

To check the *luxuriant* growth of pear trees, many schemes have been tried; but the best is here and there to strip pieces of *bark* off, behind the stem, and some of the principal branches, half round, or rather make so many wide *notches*, not going to the pith.

APPLES are sometimes planted against walls, &c.

What has been faid of pruning and managing pears is applicable to them; the branches, however, may be laid in somewhat closer; and they will not require so much room; yet they ought to have from twenty-five

feet in length of a low wall, or on a high one some-

thing less.

Cherry trees should be trained at length, four or five inches afunder. The fruit comes from spurs all along

the shoots, on one and two years old wood, which

will continue to bear. In pruning have an eye, how-

ever, to some fair shoots for successors to those that are getting diseased, or worn out. Some cut all superfluous shoots clean away, and others leave a sprink-

Mulberries are still more rarely cultivated as wall-

These trees require good room, as their mode of bearing is mostly at the ends of the trained shoots, which are therefore not to be shortened. Twenty or twenty-five feet should be allowed them, and a new planted tree is to be headed down as directed for pears, &c. Train regularly as many shoots as may be in fummer, and at winter pruning, lay them about fix or feven inches distance. A succession of new wood must be always coming forward, and of course some old taken out, for the fruit is produced chiefly on year and two-year old wood; and as it comes on spurs, and also small shoots of the same year, the leaving short flubs (of moderate wood) in pruning, feems justified, though by some much condemned.

Cherries should be found against walls in every good garden; but plant young trees, not more than two, but better if one year only from budding.

A new planted cherry tree is best to have but one ftrong shoot from the bud, and then cut down at fpring, so as to have two or three eyes on each fide, to lay in well to the wall; but if older and fuller of wood, head it down as will be directed prefently, in the article, Espalier Pruning.

ting of thort stubs, which may be allowed; but le

them not advance far foreright.

The morella cherry has a different mode of bearing from others, the fruit proceeding mostly from eyes along the branches of new, or year old wood, the pruner, therefore, is to lay in a proper supply of young wood every year, always removing older wood For the better opporto make room accordingly. tunity of furnishing the tree with young wood, the bearing branches of this tree fhould be at fix inches distance, and then one young shoot trained between, makes them three inches distant, closer than which they should not be. The morella it is clear, ought to have no stubs left in pruning, with a view to spurs, nor must any foreright shoots be suffered to grow at all, but let them be rubbed off while very young, or rather while in the bud.

The morella cherry is commonly planted against north walls, where they grow large and hang long, as they are commonly not wanted till late in the season to preserve; but if planted upon warmer walls, their fruit is finer, and (when thoroughly ripe) excellent for table use in September, or October, according to the aspect of their growth: Yet a full south wall may be

too hot for it.

\* \* \* \*

PLUMS of the finer forts are often planted against

walls, and deferve a good one.

For the pruning of plum trees, the directions given for cherries apply to them, only that the branches should be laid somewhat wider; i.e. at five or fix inches, according to the sort, as free, or less free in their growth.

\* \* \* \* \* \*

FILBERDS, or other nuts, may be trained. Lay them at full length, the branches about fix inches diffance,

distance, shortening only the shoots of new planted trees, in order to the furnishing a proper head and spread of branches, which should be kept very horizontal, to check their free growth.

They bear upon the fides and ends of the upper young branches; fo that young wood must be conti-

nually bringing in, by removing some of the old.

Currants and fometimes Goofeberries are planted against walls:

I rain the lower branches fomewhat horizontal as far as their allotted room, and then train upwards, filling the middle as they grow. Keep the branches They bear fruit about five or fix inches alunder. upon young wood, and on little spurs of the old. Superfluous thoots of the trained branches, are to be cut down to little stubs or spurs, about half an inch long, which will throw out fruit shoots and spurs. mother branches of currants and goofeberries will last many years; but when good young wood can be brought in for principals, a renewal every three or four years is necessary to produce fine fruit. Take care to provide shoots to the very bottom of the wall, that no space may be loft. In the early gathering of these fruits for pies, there should be left a sprinkling all over the trees to come on for eating ripe: I hey will prove fine.

\*\*\* One general observation may be here made: That all fruit trees mentioned fince vines, are pruned much in the same way, so that the young gardener will not find the business of pruning so intricate as he might imagine, from the number of words severally

beltowed on the occasion.

&c. in the section of the Formation of a Garden, which see, with other particulars.

## 2. OF PRUNING ESPALIER TREES.

The work of pruning espalier trees is much the same as for wall trees. The only difference is, that instead of being spread upon walls, the branches are fastened to stakes, or frames, as trellises. The fastenings are commonly ties of ozier twigs, bark of withy, bass, yarn, or soft packthread, instead of nails, which however may be used to frame work, if they are small and sharp pointed. See formation of a garden.

As trees planted for espalier training should be young, let great care be taken to set them off right at first, by regular shoots, sull surnished immediately from the stem; which is effected by proper heading down, much as was directed for wall trees. Apples, pears, plums, cherries, &c. in the general need not to be so much freed of all branches at planting, as peaches, nectarines, and apricots: There are however gardeners who prune down to the stem, all sorts of wall and

espalier trees, as peaches are. The heading down of a young tree, (i. e. apple, &c.) for an espalier, that has only one shoot from the graffing, or budding, should be so low, as to leave two or three, or at the most four eyes on each fide of the ftem, from which will proceed thoots properly placed for training. If the tree has two shoots, one on each fide, which branch out right and left, so as to be made principal leaders, cut each of them down to three or four eyes. If it has three shoots, the upper one, if not over firong, being shortened down to a few eyes, may be trained strait up, and the two lower ones shortened as above, as laterals; and thus a good foundation will be made for a proper spread of branches. If it has four shoots properly placed for training, two on each side, the lower one may be cut down, to feven or eight eyes, and that above to three or four: If the tree has more shoots, they may be either all cut out to two on each fide, shortening as before, or one (if not over XII

grong) left perpendicular, being cut down to a few yes: or if the tree is somewhat old, and has a good oot, more well-placed shoots may be left on, keeping he lowermost longer than the upper by two or three yes, making the upper ones very short. If these directions are properly observed, an espalier (or a wall) will be properly and presently filled with branches.

The best time for heading down is the spring, though when trees are planted early in autumn, it may be then done. All cuts should be close behind an eye. When a strong stem is to be cut down at spring, remember to place the foot against it, to keep the

root in its place.

Heading down is advised to be deferred till spring, not only on account of frosts possibly injuring the top eye of the fresh cut shoots; but because the head of a tree helps to push out roots. The properest time to prune the heads of new-planted trees, is, when new roots are formed; and then a head disproportioned to the roots should by so means be suffered, as the new shoots in such case would be too weak to be healthy, or fruitful. For planting espaliers, &c. See section 3.

## 3. OF PRUNING STANDARD TREES.

The principle of pruning standard trees is the same, whether full, half, or dwarf standards; and the object is, to form a compact handsome round and open head, rather small than large, equal on all sides, with tolerably erect wood, capable (as far as the art of the pruner can go) of supporting the fruit without much bending. Perfect symmetry indeed is not necessary, but consusion of branches, weak and crossing, crowded and dangling, is to be prevented by pruning; for a proper (rather free) use of the knife, is capable of doing much towards the beauty and fruitfulness of standard trees. A little pruning of standards every year, and a general one (rather free) every three or sour years, to

WO

ro

where a successional supply of young may be obtained to succeed, is the way to keep them in vigour, and have the best of fruit; for that which grows on of wood, gets small and austere. To take off large branches a thin broad chissel is proper; but if a saw is used, smooth the part with a knife.

Clear trees from moss, by scraping them with a long narrow bladed blunt knife, on a bit of hard wook and cut, or rub off bits of decayed bark, in which insects are apt to breed, and wipe the part clean. Some use a scouring brush in this business, the long end hain of which are well adapted to clean the forky parts. A bit of haircloth is also used for the purpose; and a finish is properly made to do the business well, with a brush

and foap and water.

In the first year of new planted standards, they are to be cleared in the spring, of all weak and improper shoots, reserving only a few of the strongest. If there are four regularly placed shoots opposite to each other, it is sufficient to form a good head, shortening them down to a few eyes each, or, (in general) cutting off about one-third may be a rule. What the head will be, may be pretty well foreseen, by conceiving two or three shoots to come from each of the buds below the cut.

If the shoots of the tree are weak, or the root but a poor one, cut the reserved shoots down to two eyes each. If the head is not regularly surnished with shoots, a judicious pruner will yet be able to manœuvre it into form in a year or two, and this must

be effected by close pruning the first year.

The fecond year (rather in spring) attend to the head, and cut out, or shorten, so as to provide for the suture form and strength of the tree; reserving only such shoots as recommend themselves for their position and vigour, as widely placed as may be from each other, and but sew in number. After this,

r S,

wood, his, the head will form itself, so as to need only utting clean out a few superfluities: but no shortening is allowed, except some of the lowest branches, rany one where wood is wanted to fill a vacancy; or which purpose, a weak shoot may do, cut down to see or two eyes.

If trees are too full of wood, the shoots must necesarily be drawn weak and long jointed, and so be the es fruitful, and unable to support the fruit they have; ut on the other hand, too much pruning will occasion tree to be always putting forth wood, rather than ruit, and so a medium must be observed. The branches hould be kept about fix inches afunder; and as fuperhous weak shoots will of course be cut out, so let also he over ftrong wood: for though it is defirable to have landard trees of able wood, yet those shoots that much xceed the fize of the rest, would, if lest on, infallibly weaken the others, and make an awkward tree.

Let no shoots remain on the stems, below the head, or suckers above the roots. With respect to cherry rees, rather than cut more than necessary, drooping ranches may be fuffered, as the fruit is not heavy, nd the heads of cherry trees may be fuller than other ruit trees. Wherever a cut is made in a full headed fandard to shorten a shoot, it should be (generally) at n eye fituated within fide, that so the shoot from it may oint more erectly, as the weight of the fruit is too much for those branches that grow downwards, or quite

orizontal.

Goofeberries and currents may be ranked under the enomination of dwarf trees, and the principle of pruing them will be the fame, as for other standard trees; only more frequently cutting out old wood, to make 00m for a succession of young. The keeping these rees, or bushes, more open than they commonly are, would improve the fruit in fize and flavour, and bring forwarder; yet fome of them should be suffered to row rather full of wood, in order to keep the fruit

longer, especially in a northern aspect of the garden or fome shady place; and if to this situation an fulness, be added matting or netting, they may be pre ferved till November.

The time of pruning these trees, is commonly held to be indifferent, and any time between leaf and lea may be adopted to cut them, as opportunity offers But when they are getting into leaf is (perhaps) th best time; as when pruned early, there is frequently loss of almost the whole fruit, by birds eating the buds or, as some say, insects. Leaving the whole head or till spring, is a security as to a crop of fruit, as the case would be bad indeed, if some good branches an not left, properly furnished with uninjured buds; bu still it is allowed, that an early pruning strengthens the tree, and tends to encrease the fize of the fruit.

Current trees need not be kept to open as gook berry, the branches of which, should be (for fine fruit five or fix-inches afunder, and as little thortened a possible. Those forts of gooseberries whose shoot grow in a curved manner, may have their long branches, when in fruit, supported with little forket branches, when in fruit, supported with little forker flicks. Keep these trees clear of suckers, and all shoot from the stem, that are within nine or ten inches of

the ground.

For planting standards in orchards, &c. See section 3

## 4. OF PRUNING SHRUBS.

Many shrubs are cultivated for their ornament, and fome for their fruit; of the latter kind are raspberrie and barberries.

RASPBERRIES bear fruit on little fide shoots of the present year, proceeding from stems of the last, and fometimes produce a little on those of the same, year. To prune, or dress the shrub, therefore, first cut out all the old bearers, whose wood dies, then cut out out close to the stool, all the new shoots appears the second close to the stool, all the new shoots, except three of fout

wanted for new beds, they must be suffered to me

See pages 39, 78.

The dressing of strawberries consists not only pruning from runners; but cutting down the gre leaves in qutumn (early) with a scythe; or, which better, by taking them up in the hand, and using knife. At this time they must be weeded, and it ground stirred between them, deep enough to cut it ends of the roots a little. Then there should be spre over the beds a little rotten dung, or good fresh early and all afterwards kept free from the weeds. Let us surface of the ground be stirred again in spring, as any hollows that may be between the plants silled up with earth, and some dung too amongst it, if now was applied in autumn. Thus with good management the delicious strawberry will be had in abundance an perfection.

\* \* \* \* \*

Flowering Shrubs are of great variety, and the method of pruning them is to be determined as cording to their several modes of bearing, of which consider chiefly these; that is, whether they produce their slowers upon the last year's shoots, or the present; on the ends, or the sides of their branches. It a shrub bears on the last year's shoots, it is evident that it must be cut away no more than is necessary to keep it within bounds, open, and handsome as to it form; in this case, it is the business to cut clean out or very low, what is to be spared. If a shrub bear on the present year's shoots, the old wood may, and must be cut down freely, so however as to leave eye enough for new shoots to proceed from, to make a sufficient head and show. If the shrub bears altogether, or chiefly at its ends, no shortening must take place; but if some of the branches are too long, they may be either cut out, or quite low, leaving the shorter ones to bear. If the shrub bears along its sides, the

shortening is of no consequence, and the defired

m may be freely provided for at pleasure.

The feafon for pruning shrubs is generally reckoned fpring, but autumn is better, if not too near winas at this time, tharp weather might occasion ne of the forts, (as jasmines and honeysuckles) to die un. The time of flowering must, in some measure, ect the time of pruning. Shrubs that flower in nter, (as the laurustinus,) should be cut in spring. ofe that flower in fpring may be pruned immediately, r their blow, or in summer. Those that flower, fummer should be pruned in autumn; and those that wer in autumn should be pruned either soon after wering, or in spring.

Be fure to take off in time, i.e. as foon as discored, all fuckers and over strong shoots from shrubs; by their luxuriancy they greatly impoverish the per fized branches, which are the fruitful ones, fuch large fappy wood looks very unfightly.

The height of thrubs in certain fituations, is maial, and to provide for this, the art of pruning is in reat measure competent. To keep them low, cutting wn is of course necessary; but it will be well also make the foil poor if rich. To encourage them to ount, keep trimming off the lower branches, and prove the ground by digging and dreffing occanally.

Flowering shruhs should be better attended to, as to ming, than they commonly are; for we fometimes them either wholly neglected, or cut down at ranm, perhaps, only sheared into a little form; and so y make a return quite suitable to the desert of the ner for his neglect. To be crouding full of branches, vents the production of flowers. Shrubs should not choaked up from fun and air, either in themselves, by their neighbours: The larger plants must not be tered to overihadow the less.

The general directions already given for prum shrubs might suffice, but that the young gardener must have to discover (by observation alone) the propapplication of the given rules, he is here particular directed to the work of pruning a few of the more common sorts.

Roses bear upon shoots of the present year, and up those formed after Midsummer in the past year, is chiefly upon the former. Therefore, they may, or ther should, be cut down low, leaving only three or so eyes to a shoot; except some of those short show formed the last year too late to blow then. If rose to are not close pruned, they will be unable to support the slowers properly. Use a sharp knife, and cut close hind an eye or bud. Roses for forcing should be prun in July and August.

Honeysuckles flower on shoots of the present year and therefore whether trained to walks, or kept bushes, should be also pruned close, but not so should the latter case as the former; for those against wal should be cut down to an eye or two, and those in bush

to three or four eyes.

Sweetbriars flower on shoots of the present year and therefore should be cut after the manner of hone suckles. These shrubs (and most others) are selded pruned down enough; so that in a few years they go very rambling and unsightly; but if kept compact, whave beauty, as well as sweetness, to recompence a care; and in all cases, a less number of fine flower (obtained by short and open pruning) is certainly presented to many indifferent ones.

Lilacs bear their flowers at the ends of shoots of the last year, so of course at spring must not be shortened. If got rambling and crowded, cut either clean out, overy low, what may be superfluous. If they need must reduction, let them be cut down as soon as (or somewhat before) they have got off flower, and then the shoot

yea

pt i

orti

wal

yez

ione

t, we own

refe

of th

tena ut,

muc ewh shoot hat come after will form for blow before the further is ut, for next year.

Laburnham bear along the fides and ends of old wood. Jasmines should be pruned down close, even to half n inch, and when trained to a wall, the shoots kept ather wide, like vines, (particularly the scarlet trumet fort) as they bear at the ends of weak shoots of the ear; which should therefore (as all others bearing in the same way) never be touched in summer with a mife, but be suffered to grow rude.

Sennas bear also on shoots of the present year, yet are est left rather full of wood: prune them as soon as

ff flower.

Syringa, or Mock Orange, and Hypericum frutex, ear along the sides, as well as ends, of old wood, and fourse may be shortened.

Spirea frutex, Guelder rose, and many others, bear on hoots of the year, and may therefore be pruned short.

Pyracantha bears (chiefly) on two and three years id wood; therefore the oldeft wood is to be cut out, and young in every part retained, and at length. The ime of pruning should be autumn; but early in spring will do, as the flowers may then be seen.

vill do, as the flowers may then be seen.

For the pruning forest trees, see the end of section the

enth. Berberries, see page 165.

### SECTION XIII.

#### OF HOT BEDS.

THE dung of animals, but chiefly of horses, is put together for fermentation, in order to form bodies heat for two purposes. 1. To raise vegetables, owers, &c. not otherwise to be produced, or, at least, ot in perfection. 2. To raise such things, as though

vil

VI

ve

b b

ry

1 eri

hat

110

I

eep

ay p t

be

eat

they come in perfection in open culture, yet may

forwarded by artificial warmth.

According to the quantity and quality of the mate rials put together for hot beds, the heat will be pro portioned as to strength and duration; and by a jud cious use in making, and the management afterward many advantages may be obtained from them. The great point is, to fuit the degree of heat to the natur of the different plants to be cultivated, that they ma have neither more nor less than is necessary to promote

a regular vegetation.

Two errors are common in the use of hot beds, for ing or placing in the same bed things of a very different nature, as to the climate they grow best in, and forcing with too much heat even the tenderest. Though may not answer our views of haste, the heat of a be had better be flack than otherwise. A strong hot be that ought (at least) to be made a fortnight before it used, is fometimes furnished by impatience in a for days, and various ill consequences follow, which natural

rally frustrate success.

The place where hot beds are worked should be ope to the full fun, catching it as early as possible in the morning, and having it as long as can be in the evening and if not naturally sheltered, it should be screene generated from the north and north-east winds by a boarded sence or rather one of reeds, as from a solid sence the wind reverberates; but straw, or slake hurdles, set endwise may do. A screen of some fort, (and a close clip sed hedge is as good as any) not only protects the inclose the straw of seasons and seasons are seasons. fure from the harsher winds, and confines the warn air, but keeps a rather unlightly work from view, and fing ftraws from blowing about, the litter of which is a difagreeable. In large gardens disagreeable. In large gardens, however, they have of detached grounds for the work of hot beds, where fud eig litter is of no confequence.

Working of the dung is necessary previous to the na making a hot bed; i. e. it should be thrown together

and

mate

pro judi

vards Th

fow

ghi

a be : bed e it i

fer

natu

ay an heap, in a conical form; and when it has taken thorough heat, and has been finoking or fweating or two or three days, it should be turned over, movng the outside in, or mixing the colder parts with the ot. When it has taken heat again for two or three ays, give it a fecond turn as before, and having lain he fame time, it will be in proper order for making a nature pood lasting bed with a steady heat. If in any haste, it may be made into a bed after the first heating; but it will be better for shifting again, or even a third time. When dung is ready before wanted, keep turning it ver, lest it be too much spent. It will be proper to gern egin to work fresh dung a week or ten days before it is be used; but if the dung is not fresh, it is only neces-Dunghills, from which it is defined to

Dunghills, from which it is designed to collect ma-erials for a hot bed, should be taken notice of in time, hat they are not left to work themselves weak by long moking, without opening and turning over. Beds may be

nade of dung from a week to a month old.

If heavy rain, cutting wind, or driving fnow, should the nearly rain, cutting wind, or driving snow, should eep the heaps from hearing, and the dung is wanted, and it will protect and fetch and p the heat. If at first putting it together there is not general moisture in the dung, it must be given it, by asting water evenly over it as it is laid. This may be one with a hand-bowl from a pail, but it would be etter to use a large watering pot. No water must be sent fed to dung when it is got dark; this is, however, the sincle olour that it should begin to have when put together in bed, which the directions given for working it will range it to.

ting it to.

The fize of a hot bed, as to length and breadth, is according to the frame; and the have of course) to be according to the frame; and the sight of it according to the feason, and the degree of na dry foil, a bed may be funk in the ground, from fix sether to a foot, to make it more convenient to get at

and manage. But beds made forward in the feats should rather be on the furface, for the fake of being

able to add the stronger linings, &c.

The bed should not be of greater dimensions that necessary to hold the frame up firmly, i. e. three of four inches wider every way, though some approve a making it six, which may be proper if the frame is small, as otherwise the body of dung might not hold heat enough for the necessary length of time. As a guide for laying the dung regular, (according to the fize of the frame) drive stakes, of about the height the bed is to be, at the four corners.

It is the practice of some gardeners, when they moule the bed, to take the frame off, and lay it two or the inches thick all over, and then put the frame on again. This is done to guard against steaming, and is proper when the frames are shallow: in this case, the bed mult be six inches wider every way than the frame, in order to hold up the mould for the frame to rest upon.

In case of an insufficient quantity of good horse dung that of cows, oxen, or pigs, if it is strawy, and not to wet, may be mixed with it, in the proportion of one fourth, or upon a pinch more; especially in an advance part of the feafon, or to cultivate things that are only forcing, and do not naturally require heat. In the cal of a deficient quantity of proper materials also, some of old worn-out horse dung may be laid at bottom, and little of it on the top. Offal hay may be mixed as the bed is made; or a little of mown grafs, or weeds, elp cially for late made beds; but clear straw, well wetter may be put at the bottom a foot thick, and reckons about equal to five or fix inches of dung. Cucumbers an melons have been raifed upon fraw beds, mixed with fea coal ashes; and thus the rank steam of dun avoided, which fometimes injures plants, if it do not give the fruit a less agreeable taste than they other wife would have. Sea coal ashes among dung, ha been recommended to continue the heat of the bed

feafor being

an

nd to moderate it, in the proportion of one-fifth or xth part; tanners bark has been used in the same vay; and these have been sometimes mixed generally, nd at others in layers three or four to a bed.

The making of a hot bed is performed thus: lay ome of the most strawy dung at bottom, and keep hat which appears least worked toward the middle. Let all be well broke, and laid evenly without lumps; ceping the ends and fides upright, (or rather hanging ver) not suffering them to draw in, lest the bed be nade too little for the frame, or should thus catch vet. Having laid it about half a yard high, some gardeners trample it with the feet set close, and again when raised a foot higher, and lastly when near inished; but beating it down well with the back of the fork is by many gardeners thought sufficient, exrept indeed the dung be fresh and strawy, and then order ampling ought to be used. The cleaner dung is, it must not only be more trampled, but more wetted, and the greater quantity of it used. To make beds of unfiled straw, it is recommended to lay it in a pond for two or three days, and then to throw it in a heap to drain and heat a little first.

If any dung is to be used directly from the stable, let it be equally mixed with the rest; but if there is a coldness in the other dung, it will bring the heat forwarder, by laying a good part of the fresh in the middle, which will foon kindle, and spread warmth. The litter that is made use of for this purpose should be foul; and if not, it may be made so, by mixing cow or hog dung with it, or rather by collecting the draining from a farmer's muck hill, and sprinkling with

it; which helps to fermentation. The best fort of dung is that of bean straw, next wheat, rye, oats, and barley. When the feafon is pretty much advanced, hot beds may be made of grafs mowings, (as from an orchard) and weeds, which is

a common practice in the cyder countries. These

du

Wi

the

one

heats, however, are often too violent, last not long; yet may they be lined with the same materials if done in time, otherwise if a green hot bed gets greatly coal it will not be recovered. A grass bed may be used as soon as warm, but let it not be overweighted by putting on heavy frames, or more mould than necessary. It should rather be worked with hand glasses, or oiled paper covers.

Hot beds are sometimes made of the refuse bark of a tanner's yard, and also of oak leaves; but these must have walled pits for them, of a large size, and are seldom used but in hot-houses. A bark-bed properly made, and managed by forking up at two or three months end, &c. will hold a fair, moderate, and steady

heat, four, five, or fix months.

The bark is to be got fresh, after it has been thrown out of the vats a few days, and if not moderately dry, kept a few days longer to drain, and if the weather is fair, it may be opened to the sun to dry; for it will not ferment if it is put together wet. When it is made into a bed it must be only beat together with the fork, and not trampled. In a fortnight it will have

come to a fine heat, for immediate use.

The pit should be eleven or twelve seet long, five and a half or six seet wide, and a foot, or a little more, higher than the bark in front, and two seet higher behind, to receive the mould on a body of bark, three feet deep: But if for the cultivation of any thing in pots, as there will need no mould, the pits need not be so deep, the pots being plunged in the bark: or the pit may be made level all round, of a depth to hold the bark and mould, on which frames of wood may be set. Let the pit be sunk one third, or one-half in the ground, as the soil about it is dry or not.

To encrease the heat of a dung bed when it declines, a warm lining of straw, or hay, put round it, a foot thick, and laid high up the sides of the frames, will recover it for a few days; but a lining of hot dung,

S,

rt

11

p, should be applied first to the back, and in about week after to the front, before the heat is greatly one off; and if very bad weather comes, there should ea lining of straw all round this. In cases of great eclension of heat, the ends should have hot dung applied them, or, at least, a good thickness of litter, or staw. Lay all linings a tew inches higher than the ed, to allow for sinking; or, not being laid quite so igh at first, add more afterwards, when a little settled. Carly made beds may require two or three repeated mings. Should dung of a brisk heat for a new lining e wanting, the old lining may be worked up with what there is, and if shook up with quite fresh (but oul) dung from the stable, do very well.

To decrease the heat of a bed, several boles may be made in it, by thrusting an iron bar, or a thick smooth harp pointed stake, up to the middle, which holes are to be close stopt again, with dung or hay, when the

heat is fufficiently abated.

The uses to which hot beds may be applied are various, but chiefly for the cultivation of cucumbers and nelons, for which see the next section. At the spring of the year, hot beds are commonly made use of for orcing crops of feveral vegetables, as radifies, carrets, taulistowers, lettuces, potatoes, turneps, kidney beans, burstane, tarragon, small sallading, &c. Fruits of everal forts, as cherries, strawberries, raspberries, Ac. are sometimes brought forward by dung heat; as also various shrubs and flowers, by means of forcingframes. Tender annuals, as balfams, and other flowers, that necessarily require heat to bring them up; and the less tender, and some even of the hardy forts, are also cultivated on hot beds, or other affiftance from dung, to produce an earlier blow than could otherwife be had. Directions for which, will be given in their proper places. See Sect. 18.

As to the forcing of peas, asparagus, and the raising of mushrooms, these things are not commonly practised, and it can hardly be expected in such an initiatory book as this, to find instructions for them.

### SECTION XIV.

OF RAISING CUCUMBERS AND MELONS.

#### I. OF RAISING CUCUMBERS.

See Cucumber in the next Section.

GARDENERS usually provide three crops of cucumbers in the season, all of which will be indebted to het dung to produce them; except sometimes indeed, the last sowing be upon cold ground; which, in some situations, and in some seasons, may do very well for picklers. We begin with the early crop, which is most valued.

Make a feed bed of the fize of a one-light frame, (or a two-light were better), from three to four feet thick, and if ambitious of being forward, do it fometime between the first and fifteenth of January, though some gardeners sow about Christmas: But the sooner this work is begun, the more hazard there is of failing, and the more skill and trouble will be necessary to manage them successfully.

The young gardener is advised not to attempt this business till the middle of February; and then, if he has good fortune, he will cut fruit about the middle of May. When he has attained some skill in the work, he may begin sooner; for there is nothing that professed gardeners are so fond of exhibiting, as early cucumbers, which is a proof, that no little ingentity

fing and attention is necessary to produce them. All avourable circumstances coinciding, as sowing the orwardest seed in kind, mild and sunny weather, and elenty of dung, with good frames, managed by skill and industry, early cucumbers are fometimes raised in bout eight weeks, and later in the feafon have been aifed in fix; but near upon three months must comnonly be allowed.

A bed being ready, agreeable to the directions given n the last section, which may be four feet high in fanuary, three and a half feet in February, and three feet in March, or the medium as a general rule; let it be covered with the frame and lights, raising the glasses little to let off the steam that will come strongly

from the bed.

When the heat has been up three or four days in a fingle light, or a day or two more if a two light frame, let it be taken off, and fee that the furface of the bed is perfectly level, but rather rifing behind; and if you think the bed is hardly strong enough, the opportunity is given to add a course or two more of dung. Having levelled the bed neatly with the fork, beat it smooth with a shovel or spade, and put the frame and glass on again.

The temper of the bed is now to be attended to, that it be not moulded till the burning heat is over; a judgit be not moulded till the burning heat is over; a judg-ment of which may be formed, by keeping two sharp pointed fmooth sticks thrust in behind, and occasionally. drawing and feeling them, by a quick grasp of the hand. Endeavour to hit the exact time, not putting the mould on too foon, as it is liable to burn, nor delaying too long, and so to lose time, and too much.

of that heat, the bed was made for.

The moulding is thus; lay all over the bed about three inches thick of rich loofe (not over light) and dry earth, and add as much in the centre of the light as will raise a hill eight or nine inches deep, which as foon as warm through, is to be used, except the bed

half,

feem too hot, and likely to burn; in which case, draw the chief of the mould aside round the frame, that the heat may have vent in the middle, for a day or two. As it is a thing essentially necessary in the cultivation of early cucumbers, to have rich earth, properly drh it should be prepared, and laid by in autumn, in some airy shed or hovel. Let it be, if possible, some fresh under turf earth, mixed with about one sourth part of thorough rotten horse dung, often stirred together to incorporate and sweeten.

The fowing may be made upon the hill of mould levelled down to about fix inches deep; but if any fulpicion of burning (or in fhort at any rate), it were better to fow in a small pot or two, which should be filled with the warm mould, and plunged a little way in, more or less according to the heat of the bed, for if the bed appears to be over hot, the pot may be railed from it; cover the feeds half an inch, and add a gentle pressure of the earth upon them. In a bed of proper temper, they will be up in three or four days, and fooner or later, if there is too ftrong or too weak a heat; though the age of the feed will occasion some difference. Very old feed (which some gardeners are fond of, as running less to-vine, and so reckoned the more fruitful,) will fometimes come up weak, and also rot, when the mould is damp, and the heat not ftrong; fo that feed of two, three, or, at the most, four years of age is to be preferred: That of a year old only comes up certainly, but too luxuriantly.

Whether the first feeds come up, or not, on the third day, sow a few more, and so again and again; for the early young plants are incident to failures, from various causes. As the seed must not be sown in wet earth, so if it gets too dry, sprinkle the mould to moisten it a little below the depth of the seed; but let it be with water previously set in the frame (in a bottle) to warm. Be sure to give the plants air, according to the weather, raising the lights from one

alf, to a whole inch; and now, and ever after, while here is a strong heat in the bed, tilt one corner of a ght for the steam to pass off on nights, and let a mat ang, or be nailed loosely over the open part, to keep ut the wind.

The pricking out the young plants is to be done when hey are three or four days old, taking them up careully, and the mould being warm, put three in a small ot, as the common practice is; but no more than two, r one in a small pot is a good method. If one plant only is put in a pot, it certainly may be expected to row ftronger, and be continued longer therein, and three of these may be planted close together in the fruiting bed. If only one plant is put in, fet it pright in the middle of the pot nearly up to the feed leaves. If two or three are put in, take the mould out of the pot in a bason-like form an inch or a little more deep, as the fhanks are, laying the roots fmooth towards the centre, and the leaves towards the edge of the pot; cover up to the top, and give the earth a gentle pressure.

If the mould is very dry and the bed hot, a little water may be immediately given to the roots; but if

otherwise, the next day will be best.

Give very little air the first day, but afterwards more, as the sun shines or not, or the day is mild or sharp, still or windy. As the plants get older and hardier, air may be given up to two inches, when there is a good heat, and extraordinary sine weather, to three or sour inches of tilt: For this purpose, wedges of wood, about four inches thick at the wide end, are proper. If suspicious of the air coming in too suddenly, tack a bit of cloth, or mat before the place. Air is to be given in different degrees, regularly as the weather alters in the course of the day;—a little air in the morning, more as the day advances, and less again as it declines.

Cucumbers will not do well, if the air in the bed is long confined, or stagnant: Sun is necessary as well as air, but as that we cannot furnish, every advantage that is in our power we should not fail to make use of with care. The plants are to be nursed, and preserved moderately warm, by keeping the pots plunged less or more in the bed, placing them towards the outsides of the frame when there is a great heat, and more in the middle when it is moderate.

Keep some mould round the inside of the frame, ready to earth up the pots to the rim, as the heat declines. There should not be less than two, or more than three inches depth of mould, in the intermediate spaces of the frame: for when the bed is moulded too thick, it keeps down the heat too much, and occasions hurning. Young plants should be guarded from much sun, if the season is advanced, and especially when the bed is hot. Give air.

Attend to the weather, and if rain, snow, or wind, is either of them likely to chill the bed much, provide against it in time, by laying straw round; and if the heat naturally declines much, line, &c. as directed, page 174, in order to recover and keep it up, for the plants will soon be spoiled, or lost, if the bed gets cold. They are to grow in the pots till their first rough leaves are two or three inches broad. When there is only one in a pot, a plant (upon a pinch) may grow in it till it blossoms.

Use water (soft) but moderately at first, till the roots get spread about the pot, and then wet the shanks of the plants as little as can be helped, if the season is early, or there is little sun. When the roots are got to the bottom of the pot, take care to water to the bottom; but over-much watering of young plants makes them sickly. Once a week, at an early season, will be sufficient, except the heat is very strong in the bed, and the weather very sunny: the water must be in a small degree warm,

bed is warm, and s

warm, and given in the morning towards the middle of

If the feed bed is not likely to hold the plants so long as directed, (or nearly) in a free growing state, an intermediate bed should be made in time to receive them; for it is not proper to plant them out into the fruit bed too soon, lest there be a failure in keeping up its heat to set the fruit, and bring it on. This intermediate bed should be made of proportionate strength, for the time it is wanted, and may do at two and a half, or three set thick; nor need there be any great objection to an intermediate bed, as it tends to insure success, and brings the plants on faster, and saves trouble in keeping up the heat of the seed bed.

Burning is a thing to be suspected when a bed is very hot, and in proportion as the mould is damp; and should therefore be feen to, by drawing away fome mould from the bottom near the middle; and if it appears discoloured, of a greyish hue, and caked, let what is so be taken out from all parts of the bed as foon as possible; but take care that in doing it, too much cold air do not get in and damp the bed, or injure the plants. Do this work at the best time of the day, while the sun shines, if it may be, and rather at twice, allowing an hour between. Fill up with fresh and dry mould, and keep the glaffes close, till the earth is got thorough warm. again. Burning, however, is not of so much consequence now, as when the plants are put out to fruit, for the pots may be drawn from the evil; but burnt mould contaminates the air, as well as injures the roots that it reaches to. See Burning again prefently.

Steaming must be guarded against, and the rank effluvia which rises in the bed at first, and whilst the dung is quite hot, must have uent night and day, by raising the lights. A little rise will do on nights; and if a mat hangs before the aperture, or is nailed down loosely over it, the too sudden entrance of cold air will be prevented. But when the strong heat of the bed is certainly over,

shut close on nights, and give but little air in unfavourable days. Rank steam is sometimes drawn into a frame from the outside of the bed, occasioned by the matchanging over it; therefore, in covering, it is necessary to keep up the ends of the mats, so that the glass only be covered. Danger of steaming arises also from the application of fresh linings, the smoke of which, wind may drive into the frames; so that the lining should either be covered with two or three inches of mould, or which is better, a good thickness of fine hay. Sometimes steam will insimuate itself round the frame within, through the bed settling unequally, so that the mould draws from it: Prevent this by filling up the apertures.

Covering up at night has been just directed to be only over the glaffes, for a reason given. Put the cover on a little before fun set, and take off a little after sun rife, except very bad weather dictate otherwife; yet remember, that light is a most necessary article in the welfare of plants, and guard against permitting cover longer than compelled to it. While the bed is in a good heat, one mat is fufficient, but yet if the weather is sharp, more should be used; for if not necessary for the warmth, it will be useful to keep the steam of the bed from being so suddenly condensed as to drop on the plants, which would injure them. As the bed declines in heat, and the weather is cold, a thicker covering must be put on; and a very warm covering is made thus:—lay on a mat, and over it a coat of straw, or rather hay, and then a mat on the top, which tack down round the frame. It will help to warmth, to push into the dung some little sticks round the frame, and fill up the space with hay. Covering round the bed with ftraw and lining have been spoken to: let the applications be made in time.

The feed bed, by good management, may be kept with a good growing heat for fix weeks, when the plants

plants being about five weeks old, will be ready for

butting into a new bed to bear fruit.

Stopping the plants is to be performed about a week before they leave the feed bed; i. e. as foon as the fecond rough leaf is expanded, and shews in its bosom the little bud, or eye, that produces a runner. This is to be nicely cut off with a pen-knife, or small sharp pointed scissars, or picked out with a needle, though, if it gets forward, it may be pinched off. Soon after this operation, the plant thickens, and will push for runners again, which the stopping is designed to dispose them to; and the effect is an earlier and more plentiful bearing. The practice of stopping is again to be performed upon the first runners when they have three joints without shewing fruit.

The fruit bed comes now, and it should be made of good materials, duly prepared, and well put together, towards four feet thick. It ought not to be of a fize less than for a two-light, but better for a three-light frame; as the heat is more certainly to be kept up a proper length of time, in a full fized frame, without which all the previous labour is lost. Preparations must be made for this bed at least a fortnight before it is

wanted, in the way directed in the last section.

Before earthing, take care that the burning heat is over, and that the mould to be used be properly dry. Lay it all over the bed not more than three inches thick, (for reasons given, page 180) making hills where the plants are to be set about twelve or sourteen inches depth. A two-light bed (of proper materials) will not be ready for moulding in less than a week or ten days from making; nor a three-light in less than ten days or a fortnight. But if it should be desired to plant out quick, on account of the seed bed having got cold, a security from burning the plants is found in forming a hole in the bed, where the plants are to be, two inches deep, and about a foot, or fifteen inches over, and filling up with fresh cow dung; through this the heat will not burn,

burn, and if it catches the other parts of the bed, the disease may be easily remedied, in the way before mentioned, without disturbing the plants. Some gardener place turf under the plants, with the grass downwards to prevent excess of heat; and it helps to keep the mould, in other parts, from burning, to stir it about in time. A preventative used by some, is to put on a layer of five or six inches of old dung, when the bed is made. It should seem, that a layer of about three inches of old bark might prevent burning. See Burning, pages 180, 181.

Planting is to take place as foon as the heaps of mould are warm. Spread the earth on the top a little, and having the hills a full ten inches depth, makes hole in the middle fix inches deep, to receive the pot of plants; which pots will be from four and a half to five inches deep, and confequently the plants funk in this hole a full inch more in mould than they were in the pot; and they will have four inches depth of mould at the bottom, which there should be below the roots. Draw the mould up to the plants, and press it gently between, and to them all round the hillock. It is spoken here of a pot of plants with three, but if only one in a pot, the whole hill must be thrown down to four inches depth, and the plants, with all the mould, fet one close by the fide of the other, and then filled up and round with the earth of the bed.

To shift plants out of the pots with the ball of earth entire about them, put the fingers between the plants, and turning the pot up, give it a gentle tap on the knee, or edge of the frame, and the whole will come out; a little pressure at the same time through the hole at bottom, with a finger of the other hand, will assist: turn the plants up carefully, and place them in so. To secure their coming out whole, water the pots to the bottom the day before; and if not too wet, they will slip out. If the plants hold tight to the pots, when turned up, a long thin narrow bladed knife will be

proper to loosen the sides. If the mould should fall om the plants, carefully spread the roots in planting, d they will be fure to grow, only their having no the ey have struck root again. Thus having fettled the ants, shut the lights close till all is thorough warm, if then give a little air; if the mould put round the

Management as to air, covering, watering, lining, ad guarding against burning, steaming, &c. is now to cupy the constant attention of the gardener: On these ads, what has been before faid may ferve for instrucon now; only as the season advances, and the plants at strong, the more air and watering may be ventured a, and if the heat of the bed is good, less covering will b. As the season advances, water earlier in the mornig, or later in the afternoon, so as not to have a full the in come directly upon the leaves while wet; for drops dat if water act as convex glasses, to draw the rays to a cus, and thus scorches. As the weather may be cool, the bed gets cool, water the more sparingly; and in his case, especially, avoid wetting the sbanks of the lants much. It will be known when water must be iven, by the larger leaves flagging, without any vioent fun to occasion an extraordinary perspiration. Botes of water may be kept in the frame, which is preferble to that warmed at a fire; yet the latter must be fed when there is not enough of the former, to water deeply as necessary. When the frame gets full of ine, it gets full of root; and as by this time the days et long, and may be funny, a good portion of water or the whole may be wanted twice, or, perhaps, thrice week, from a watering pot.

Air should be given (as before directed) in fine weaher to a tilt of three inches, or more. While there is brisk heat in the bed, give a little air on nights. If he bed gets cold, it may be helped by covering up arlier and warmer, and uncovering later; though the

plants should not be deprived of more light than made

necessary, through bad weather.

In case of burning being discovered, take the burn mould from under the plants carefully, but quickly, a far as can be, without throwing them down: remember to be cautious of stearning, and think of lining (180) in time, that the plants be not stunted by cold, for when they are materially checked, they hardly ever recover it. Sometimes the application of linings will so increase the heat as to occasion burning; let this be seen to, and (at least) remove a part, and remake it when the violent heat is abated.

Earth up the shanks with dry mould, (kept in the frame on purpose) as the plants increase; and let warm mould be added to the sides of the heaps, as soon as ever the roots begin to appear through, or the runners need support; proceeding thus, from time to time, till the bed is filled up level all over. For this end, keep bringing in a little cold mould frequently, laying it round the sides of the frame. When the bed is filled with mould, it is a good way to press it tightish round the frame, about a hand's breadth, to keep the roots longer from the outside.

Some gardeners mould the bed all over, as foon as they are fatisfied there can be no more burning; but it is best to do it at several times, and not sooner than is necessary to cover the roots, and support the runners; because, where the mould lies thin, the heat comes up better to warm the air in the frame, for the leaves will

want warmth as well as the roots.

Train the runners close down regularly with next pegs, as they proceed in growth, and prune the tendrils off as they appear, but take care not to break any of the leaves. When the days get long, and prove very funny, the shade of a fingle mat, for two or three hours in the middle of the day, will be proper, as suppose from eleven to two.

Thus

Thus very particular directions have been given, but much will depend upon circumstances, and diftion must direct. Let it be remembered, no neglect I be borne with. If any imprudent person should the lights high, to pry into the bed in improper ather, perhaps an early tender crop might at once eive their death blow, though exposed but a very ort time. Success in raising cucumbers and melons efly depends upon keeping the bed in due temper; the ints being neither burned nor chilled.

Setting the fruit is the practice of most good garners, as generally infuring the embryos from going , as they are apt to do at an early feafon; when t much wind can be fuffered to enter the bed, and no es or infects are about, to convey the farina from the the flowers to the female. The male flowers have en ignorantly called false blossoms, and so have been gularly pulled off (as faid) to strengthen the plants, tthey are essential to impregnate the female slowers; e. those that shew the young fruit at their base: This pregnation, called fetting the fruit, is artificially done

fast as they die upon the vines. Lay a bit of tile,

fome fuch thing, under forward fruit.

Something of pruning may perhaps be necessary, plants will not bear well, either in quantity, or quality if the frames are crowded. The rule (of course) is, cut out those runners that can be best spared, as bein weak, most in the way, or having the smallest fruit But as the fulness is generally owing to the putting in the bed too many plants, the better method to cut down to the root a whole plant; and that in time i. e. on the prospect of being too full of vine: this m feem a great facrifice, but it will prove a profitable on Let the discharged plant lay a day to wither, that hang not to the others, and break their leaves, in draw ing it out while fresh. About Midsummer, the fram may be raised, to permit the runners to strike out, and a fortnight after taken entirely off; though once in frame, and always in, is better, if convenient,

A SECOND CROP of cucumbers may be fown at an time between the middle and end of March, if the are to be brought up in frames; but if under hand glasses, or paper covers, then any time from the beginning of April to the middle, is soon enough, at least in Northamptonshire. A hot bed, for fowing the seeds this time, need only be from two and a half to the feet thick, and a one-light frame. On this bed all may be fown, in pots, or otherwise, tender annual and it is a very good time for most of them. Or the feed for plants to ridge out under hand-glaffes, may b fown in pots, and placed in other hot beds, to bring the forward till they have been stopped.

What has been faid about making hot beds, an fowing, and managing cucumbers, will direct now only at this feason, mowings of grass may be pround a bed to increase the heat, and will be found usen

to lay on the top of dung linings, when funk.

CU

cold

our-

able

ole fituation, and fow in patches eight or nine feeds in a ole, formed like a shallow basin, covering half an inch time eep; and if covered with hand glasses, to bring them and pa little while, it were much better. Thin them then getting into rough leaf, to four or five of the best lants; spread them a little, and earth up to the seed aves, giving a little water; and if, afterwards, the umber of plants is reduced to three, it might be better nan more. Give plenty of air by day, and a little on even ights. Raise earth about the shanks as they grow, nd let it lie about them, while the plants are small, in the form of a shallow basin. There should be a good

he form of a shallow basin. There should be a good dung hany holes, to produce picklers enow for a gathering.

As to saving the seed of cucumbers, as it is of some will onsequence to be ascertained of a good kind, when he early nature and approved quality of any fort is deep nown, it ought to be an object to save it well; which whe will be best done from plants of the second crop, that ind ave been ridged out, i. e. brought up under hand lasses. From this crop that plant which shews fruit rest (under the same culture) should be reserved for ted, judging that its early disposition may be continued, as a supposed to save the series of the second crop, that which shews fruit rest (under the same culture) should be reserved for ted, judging that its early disposition may be continued, as a supposed to save the best seed.

ways produces the best seed.

Fix upon handsome fruit, and prefer that which is laced lowest, or grows nearest the root. Leave no nore than one fruit for feed upon a plant, and let it emain on the vines through August, or as much longer the weather will permit, to be very ripe: when cut ff, place feed cucumbers against a fouth wall, till they

ppear decaying.

Being got rotten ripe, scoop out the pulp and feed into ome vellel, and stir it well up, which repeat for several ays; then let it be washed in two or three waters, thich will separate the pulp, and leave the seed clean: read it thin for two or three days, that it may dry horoughly, and putting it up in paper for use, keep it in place free from damp. Let it be every now and then

examined and rubbed in a dry cloth, and it may be to for feveral years.

#### OF RAISING MELONS,

#### See Melon in the next Section.

MELONS are raifed much in the fame way as cumbers. They should not, however, be thought fo early, and from the middle of February to the mid of March will (for most persons) be soon enough fow them. The place where they are cultivated that be well sheltered, so that winds may blow over t frames, as mentioned in the directions about hot-be They require a stronger foil to grow in than cucu bers, and more heat, both at bottom and top, and no less water: they take up more room, so that one plan Cucumbers may be raised on a feed bed till fix to pla out on the fruit bed; but melons will (generally least) require an intermediate bed. During the who time of the cultivation of melons, (till high furame they must have a lively bottom heat, in order to brin them forward, and fucceed well; and, if melons are last as foon as September enters, a lining of hot dung may put to the bed, to afford fome degree of heat to outer roots, as an equivalent to the failure of the feafor Melons never do well in a shady summer. As cuch bers are about three months coming in, fo melons a about four. They fet their fruit in about two month and are about the same time in ripening, though for days will fometimes effect it.

The feed of melons (procured from well ripened as fine flavoured fruit) should be about four years of though some prefer it much older, as judging it so much the less likely to run to vine: If it is too old, however e ke

comes up weak, and is apt to rot, when the mould is ot fufficiently dry, and the feed bed not very warm. new feed only can be had, it should be carried a week two in the breeches pocker, to dry away fome of the fore watery parts: The earlier the feed is fown, the der it should be. Melon feed may be fown in a cuimber bed, that is in a brifk heat, in pots plunged wards the middle; but a bed should be ready to move he young plants into before the cucumber bed gets too bol. Sow only three or four feeds in each pot, and over a little more than half an inch: The earth in hich the feed is fown, fhould not be fo ftrong as that which the plants are to grow for fruit. When the edlings are three or four days old, take them up careilly, so as not to break any of the roots, and either lant one in a small pot, or two in a little bigger; but epend on no plants which do not appear healthy and rong. Sow a few feeds every four or five days, left cidents happen to destroy the first plants.

As melons require skill, and occasion trouble to raise tem, the greatest possible care should be taken that the ed is of a good kind. Melons should never grow near numbers, especially if for seed, as the farina of the cumber may impregnate the blossom of the melon, and we it a watery slavour, or quite alter the nature of

Though melons may be fown in a cucumber frame, at is in a good heat, yet rather make a feed bed, of bout three feet thick; and having put on the frame ad light, tilt the glass a little, and when the great heat abated, put on some dry, rich, and fine, but not very ght earth, to the thickness of four inches all over; and the next day, if the mould is not too hot, sow the ed, some in the beds, and some in pots, placed just in a middle, which may be drawn up out of the way of y burning heat.

When the plants appear, give them air, and beware rancid feam from the glasses dropping on them:

They may be wiped with a woollen cloth, or turned to dry in fine weather. Confider what was faid about cucumbers, concerning too much heat, too little, &c. After the melons have been up two or three days, (a was faid before) let them be potted and plunged to the rims, towards the middle of the bed; and the next day a little water (warmed in the bed) may be given the roots; or a little may be given at the fame time, if the

mould is quite dry.

As soon as the plants are potted, think of making a second bed, to be ready in a week, ten days, or fortnight, (as circumstances dictate) that so the young plants may receive no check through a decline of hear in the bed where they are. This bed should be stronger than the seed-bed, and rather for a two-light frame; and being moulded as soon as it can be, not to burn, so the pots in, about an inch deep, and in a day or two draw a little mould up round them, and so on again But if the first bed is warm enough to hold the plant longer, the heat of this second bed (if violent) may be suffered to evaporate a little more first. Here they are to grow till in the second rough leaf, when the plant should be stopped, as was directed for cucumbers.

The third, or fruiting bed, is to be (observe) read by a few days after the time of this stopping the plants. It should be a strong bed, of four feet thick, and for a three-light frame, and made the higher, the most strawy the dung is. As soon as the burning heat is sufficiently abated, let the bed be covered all over with good dry melon mould (the best is a rich moderate) strong loam) three or four inches, and heaps made under each light of about fourteen inches depth. Melons do not fruit well in a light mould, but yet it should not be a heavy one. If the mould is thought too light, let is be pressed a little together to give it consistence.

To a fresh maiden soi!, or good earth from the kitcher garden, that is known to be in heart, (by the strength of the plants it has produced) add about one fourth, or

ne third, of well confumed dung, and it makes a good inpost, but it must be completely incorporated by freent turning and exposing to sun and air, and kept by me means dry, as under a shed, &c. as directed for numbers. Much depends on the melons growing in

The planting of melons takes place as foon as the ills of mould are warm through; only if a violent eat is in the bed, a day or two's delay does not fignify, the plants are doing well where they are; yet the ots must not be cramped longer in the pots than ceffary. Melons require a greater depth of mould to low in than cucumbers, and the bottom of the roots, planting, should not be nearer than five or fix inches on the dung. Shade them from much fun, till they we taken root.

If the lights are small, one plant under each is sufcient, and if large, let there be only two; for melons quire much room. It is a great error in the cultivative of melons not to allow it them. Earth the plants by an owith dry mould about the shanks as they proceed in solant with, and bend them gently down with pegs, to give em a regular and snug direction all over the bed.

Then fruit is set, there must be only one of the large,

lants of two of the small sorts, (fair and promising) left on

the state of the small sorts, (fair and promising) left on

the state of the second, or rather the third joint above it, which

cat is called stopping.

With Pruning is necessary, in order to strengthen the

rately arers, and keep the frame from getting too sull of

under the, i. e. let all very strong, and all weak shoots be

their leaves disturbed or damaged, to put them in order A piece of tile, or a small earthen plate, under eat fruit, is proper, to keep it from the damp mould, as to affift its ripening by reflected heat. Three (at the most four) melons are as many as should be left to grow upon one plant; and those are best which are situate nearest the stem, as remote ones are not so well not rished. Do not let a great deal of vine grow below them, lest they be too much robbed, and let them h stopped as before directed, for when there is a great length of vine above, nature puthes towards the extra mity, and passing by the fruit below, forms more above sometimes to the total loss of the first set fruit.

Keep mould round the fides of the frame, to earthu the plants to the very leaves, and round the hills, little at a time) as the plants increase, and do not early all over the bed before it is necessary; for full earthing has at first is apt to occasion burning, and afterwards t damp the heat of the bed too much, diminishing also the earthed all over, press the mould all round the sides of the frame, about the mould all round the sides of the frame, about the mould all round the sides of the frame, about the mould all round the sides of the frame, about the mould all round the sides of the frame, about the mould all round the sides of the frame, about the mould all round the sides of the side the frame, about fix inches wide, to make it firm, the the roots may not get too foon to the wood, and mat to

much against it, which occasions sickliness.

much against it, which occasions necessarily melons, without T plenty of dung both for beds and linings. The particle of the plenty of dung both for beds and linings. The particle of the plenty of dung both for beds and linings. lars of management, concerning covering, shading, an lining, stopping the young plants, setting the fruit, it om and to guard against burning and steaming, may be set with in the directions already given for cucumbers; only it is air, and much less watering, will do for melons. Ke them close that down on nights, when the heat of the bed is become moderate, and cover well. As melon therefore, are kept rather dry, they should be shaded little in very sunny weather by a single mat, for two three hours in the middle of the day; i. e. when the state of the day; i. e. when the state of the day; feafon is forward, especially if the bed itself be in a h frate. Mela

order

Melons may be watered moderately once a week, in early in weather, or twice if sultry, especially if the mould light. Early in the season, water a little before to soon, and in high summer a little before evening. When the fruit is setting, and when getting towards in the season, very little water must be given: be sure to now rater the extremities of the roots, but avoid the shanks, well articularly while the plants are young. A little or inkling all over the leaves, when the plants get big, gree but let not a hot sun shine upon them at the time) will greatly refresh them, when it is not thought probove er to water the roots thoroughly, on account of the ed being cool. Because much wet is certainly injustitudes, some gardeners keep their melons exceeding dry; Melons may be watered moderately once a week, in ed being cool. Because much wet is certainly injusting ious, some gardeners keep their melons exceeding dry; alls, at their leaves should not shew too much sign of drought, east est the fruit shrivel for want of moisture. Take care thin hat the heat is kept up at the setting of the fruit, or it will become yellow, and fall off. Preserve a good bottom eat till about Mid-June.

Melons should not be turned so much about, as is the sactice of some gardeners, in order to ripen the fruit that lover; for it hurts the soot-stalk, distorting its vessels at to hat feed the melons, and so preventing a proper digesion of the juices.

1elo

into the flavour of a melon being preferable to the fize, without the reason why water is to be withheld (as much as an be) when they are ripening: with it they will become bigger, and so appear finer; but what is quantity in the young fruit need not be fully exposed to the Kee an; it had better be a little covered with leaves, for such hot sun hardens the skin, and prevents its proper wowth. When a melon has nearly attained its size, and hen, however, a full sun is necessary to ripen it.

As to cutting the fruit, if it is to be some days before

As to cutting the fruit, if it is to be some days before ent melon is eat, (as when carried to a distance) it should a hoot be quite ripe. Its ripenels is known by the high colour, and strong odour, and the cracking of the soot-

Vour

ved) from azed s put on a ufed

ng them to our use, by an unnecessary preference to ther foods. "There was a time, when bread and erbs (with a little fruit) were the only dainties wherewith the tables of the greatest voluptuaries were pread."

" Vegetables and fruits were our innocent, primiive, and natural food; but men's depraved appetites have substituted the shambles; yet, after all, the invenions of the most luxurious and voluptuous epicure, the nost Cafarian tables would want of their magnificence, hoble gust, and grateful relish, without fruit and the productions of the garden, which gives the true condiment, and most agreeable closure to all the rest."

"Their use is all our life long, of that universal importance and concern, that we can neither live nor fubfift in any plenty, with decency or convenience, or be faid to live at all without them: whatfoever contributes to delight or refresh us, are supplied and brought forth out of this plentiful and delightful store of the garden."

Let it be a rule to gather vegetables of all kinds (defigned for the table) in the morning, before much fun has shined on them, and lay them by in a cool place

till wanted.

ALEXANDER is a culinary plant, formerly much used, but has given way to celery; like which it is blanched (about a foot high) for use in soups and sallads. The feeds are best fown in drills two feet asunder, and thinned to fix or eight inches distance, though they may be fown at broad cast and transplanted. Spring fown plants come in for autumn, and autumn ones for the use of spring.

ARTICHOKE, there are two kinds of, the globe and the conical. The latter is the hardiest, but the former is generally preferred, both for fize and flavour. Artichokes are propagated from rooted flips, or offsets in

ĭ

April, taken from the mother plant, by drawing the mould aside. As they require a rich soil, and are stationary plants, dig a good quantity of dung in completely below the roots for them to strike into, breaking the soil well with it.

The head of the artichoke is valuable according to its fize and substance, and therefore to a good soil, add good room; for though they may be planted nearer, yet they would do much better in rows fix feet afunder, and three feet apart in the rows. Between these rows may be propagated feveral forts of fpring or early fummer crops. They will reward the trouble of being regularly watered in dry weather; fuffer them to bear only one principal head. Fresh plantations should be made every third or fourth year, to have them in perfection. Every year that they stand after planting they should be dug deeply round, and some well confumed manure applied. Cut the heads when the leaves begin to expand, and before the center opens for flowering; and let them have about a foot of stalk, breaking the remaining part of the stem down to the bottom, that it may not rob the root by a waste of sap. At the spring dressing, all the suckers are to be taken off, leaving three only of the strongest shoots to fruit. Those without roots will grow by planting deep, and keeping moift.

Let the plants be protected from hard frosts; at the prospect of which, cut down the stalks and outside leaves to the inner ones, dig between, and earth the plants to near the tops; and if severe weather follows, they should be covered thick with straw, which must be removed when the frost goes. The earthing-up need not be levelled down till March, or may be let alone till the time of their dressing, which is best done at the beginning of April. If uncovered early, let the litter lay by ready in case of frost to cover again.

To have a long fuccession of artichokes, some slips should be planted at two different times every spring,

as they bear the same year, only come in later, and with smaller heads than the old plants. If being planted late, they do not produce in the present season, they come forwarder the next summer than old stools do; but remember, a good soil and open situation are absolutely necessary for the artichoke. 'Tis of service to lay grass mowings, or some litter, about the roots to keep them cool; for though artichokes should not be planted in a moist soil, on account of frost, yet they thrive best in a cool one. Artichokes that come late, may be cut with their sull stalks, and being laid up to the head in moist sand, in a cellar, will keep a month, so that they may sometimes be had at Christmas.

Asparagus, there is (in fact) but one fort of, as an esculent; but some difference occurs as to size, colour, and flavour, arising from cultivation. In order to obtain large heads, and to have the beds continue to produce the longer, much dung is used; but the less of it, the sweeter will this vegetable be, so that in a soil

naturally prolific, no dung need be used.

Asparagus beds are commonly made from plants, but the preserable way is from seed, which will be best had from Gravesend. The time for both is March, rather early in the month than late, though the beginning of April may do. The plants should be only a year old, and set in rows a foot distance, and the roots

the fame, or a little less in the rows.

Making the beds four feet and a half wide, there will be four rows of plants, and nine inches left between the outfide rows and the alleys, which should be two feet wide. The beds ought to be trenched full eighteen inches deep, and enriched with dung that is well consumed, burying it below the roots; they will soon strike into the dung, which had best not lay immediately about them. If some mould of rotted vegetables, wood pile earth, in the stronger soils; and a little pond mud in the lighter, were mixed with the top soil, it would greatly help the plants; or if none

through the whole work, it were better. As asparagus beds are designed to last many years, (suppose twelve or fifteen) no pains should be spared to do the work well; and if the ground were prepared sometime before hand, or in winter, it would be an advantage, the top soil laying trenched for the benefit of frost. The alieys, as well as the beds, should be made good, for the roots of the outer rows will strike into them. A rich sandy loam is the best soil for asparagus, and if the earth is too heavy, or too light, rectify it. The stronger the soil, the higher the beds should lie above the alley, and more rounded; and in very light soils they should lie stat, or rather sinking, to catch the rain.

To plant beds of alparagus fet the line nine inches from the edge of the bed, and cut the trench upright, close to it, so deep that the crowns of the roots lie full two inches below the furface. If the mould of the bed lies light, and is likely to fettle much, the crowns of the plants may come to the top, and two inches of mould put on afterwards, which is indeed the belt method of planting; but if the ground is not expected to fettle, two inches of the top mould must (in this method) be first drawn aside to cover with. The roots must be neatly spread against the trench, and cut as little as possible; i. e. only the damaged parts off. This should be with a sharp knife, and it would be better if done the day before they are used, that the ends may dry and heal. It is of confequence to have the plants dug up carefully, with a three pronged fork, that the roots may not be injured.

To fow beds of asparagus, make little holes an inch deep, at the distance directed for plants, and having laid three fine seeds in each, near an inch asunder, cover them three-sourths of an inch, which will leave little hollows, to shew their places, and give occasional watering in a dry time, to setch them up. If the beds were covered with a little haulm, or straw, till

e plants appeared, it would help them to germinate, in a funny feafon they are apt to lie long, especially the work be not done till April. When the plants e above ground fill up the holes. Refresh the plants calionally with water through the fummer, and when ev are two inches high, thin the holes to one plant each, and cover the beds with an inch of mould, nd they will then be two inches deep, as was directed r plants. The drawn plants may be pricked out at our or five inches distance, to make good any deficincies next fpring, or otherwife; but if the plants are or wanted, it will be best to cut the spare ones off, thich does not disturb the roots of those left. In Offober, when the haulm is decayed, cover the bed rith about half an inch of rotten dung, to make them rong and keep out frost; and, in severe weather, put ome long litter over all. In spring, take the litter off, and gently ftir (with a proper fork) the rotten lung in: do so again the next year. Watering aspaagus beds with the draining of a dunghill (a rich taxure too often lost) in autumn, or spring, will wash own to the roots, and greatly benefit the lower foil to he increase of the produce: It is worth while to make rank dunged water for this purpole, for weak or old eds. See p. 53.

Asparagus is cut from planted beds in three years, and from sown ones in four; but this loss of a year, will be amply repaid by the superior fize and abundance of the heads. If the buds come very fine, a little may be cut the year before. A thin crop of onions, or of attuces to prick out, is commonly had on planted beds the first, and on seed beds the two first years, taking are that none grow just about the plants. The best method of doing this business, is by an intermediate will between each row, and again across them: It were

better however to have no crop at all.

The management of asparagus beds is, to cut down the haulm, within an inch of the ground, when it

turns yellow in autumn, clearing of weeds, stirring the ground, and covering the whole over with about an inch-of rotten dung before every winter, which i to be forked in at fpring, not to hurt the plants, and covered with fome parings of the mould from the allen which should afterwards be dug over, if no crop is in them to prevent it. It may feem, that an addition every year to the beds might fink the crowns of the plants too low; but it is their nature to rife as the grow. Besides the rotten dung, as above, there may be laid some long litter over the beds, before severe weather fets in; but the covering of asparagus beds i not fimply to keep out frost, (which will not hurt them without much wet) but to keep them warm, that the buds may be forward at ipring. A flump ought to be kept at each corner of the beds, to shew their bounds and as marks to pare the alleys up by, which (generally) should lay three or four inches lower.

The cutting heads of asparagus should be carefully performed, not to injure adjoining buds that are starting up. Move the mould a little aside to see, and then close by the head, and with a little slope, cut it off about three inches below the ground. The knise should have a long narrow blade, and a proper one is indented with teeth as a saw. It may be cut, when from two to sour inches high; and let it be regularly done as soon as ready: If it is lain by in a cool place, as in a dairy or cellar, it will keep very well three

or four days.

Six rods of well planted ground will produce, in the full feason, about a hundred a day; and this, as a rule, will help to determine how much room a private family

should allot for this vegetable.

BEANS we have several sorts of, differing in size, colour, slower, slavour, hardiness, and time of coming in. Of the forward beans, the mazagan is generally preferred, as the earliest, hardiest, most productive, and pleasant. The Portugal ranks next to it. Of the later

the ter

ater forts, the Windfor stands first, as to general estination, for eating; but it is in most soils rather and dle bearer. The long-pod and Sandwich, however, are preferred by some, chiefly as more fruitful. Trials must determine taste; but it may be observed, that the white blossom bean is a very good one, if eat young.

Close under a warm wall (to which they should be kept by packthread) some mazagans may be put in the ground early in October; but at the latter end, and the beginning of November, is surest, when they commonly succeed at some distance from the wall, earthing them up regularly as they proceed in growth. Crop the tops off as soon as the lower blossoms are full out, or begin to fade. This forwards them.

Put the *small* forts of beans in three inches deep, and four asunder, in fingle rows; or fix inches asunder every way, in double rows; and let the rows, in the first case, be two and a half, and in the latter, three

feet afunder.

There is a dwarf bean (by some called the fan-cluster) that grows but a few inches high, which is very convenient to put in, close under a fouth wall, in October, and they will thus be but a few days (if any) later than

the mazagan, fown in November.

'Tis a good way to sow patches of beans in a warm corner to stand the winter, placing them about an inch from one another, and transplanting them at the above distances, the first mild weather after Mid-February or in March, to any sheltered part of the garden, and if under a south wall (not too near) it will sorward them, especially if watered in a dry time. Beans, sown in patches, may be easily covered in severe weather, by a frame, &c. Make trenches to lay them in when transplanted; pull not off the bean adhering to the roots, shorten them a little, and put them in rather highly covered over the shanks. If planted assant, they will soon get erect; but this is only permitted

mitted in case of a shallow soil, or long shanks a

In fevere weather, a light covering of peas haula, or any straw, may be lain over winter beans to protect them, but must be taken off as soon as the weather

alters; for too much covering of any thing is as likely to destroy (eventually) as being wholly exposed.

Though the mazagan is mostly the bean put in to stand the winter, some gardeners sow other forts for the purpose, (even Windsors) which may succeed; but they certainly will not come in so early by near a fortnight, and must have a dry sheltered situation. The larger beans must be sown a little deeper, and two of three inches farther asunder than the mazagan, allowing a soot more between the rows, especially if double ones, which are best.

If early crops of beans fail, through feverity of the winter, be fure to take the first opportunity of open weather in the new year, to sow some of the early sorts; and if they be covered over with some straw, they will come up the sooner; but remove the covering as soon as the beans appear, if not frosty at the time. Or if a hole be dug near a south wall for two or three barrows full of hot dung, covered with six inches of mould, beans may be set very near one another, for planting out, cover the work with straw as before, and thus time will be gained, especially if the beans be soaked a day and night in a warm room.

Succession crops of beans are to be sown every three weeks, or a month, from November to July; preferring the larger sorts in February, and so on to June, when the smaller (or early) kinds will be the properest.

BEET, there are four kinds of, red, green, yellow, and white, which are used several ways, as pot and sallad herbs. The large leaves of the white and yellow are sometimes blanched, when sull grown, for the sake of their thick ribs, being peeled for stewing, and eat as asparagus, and called chards; some say the yellow

ellow is best, though the white is most commonly e fort used. Sow beets in February or March, thinly, ther in drills or broad baft, and hoe them to a foot under: They run to feed the second year. A little so may be fown, early in autumn, for late spring use; ikely at they will be small. The red fort is cultivated for s root, and is preferved in winter, in dry fand, as arrots are; and of this there is a turnip shaped fort, hat fuits best in heavy shallow foils, and a long rooted ort proper for light and deep ones: Beets, but prinipally the red, require a rich foil.

BOORCOLE, or cale, is a hardy green, of which we ave two principal forts, green and brown, and a little ariety is in the leaf, as plain, curled, variegated: The atter is a pretty vegetable when growing, but not fo

ardy, or so pleasant, at table as the other forts.

Some fow two crops of this green at the end of March and of April, but one fowing may suffice; and he first day of April, or at least in the first week, is he best time. Sow in an open situation, and in cool ground, and thin the plants in time, that they may be robust, and able to support themselves.

This green should be planted out in rows a yard funder, and two feet apart in the rows, having been previously pricked out from the feed bed, at fix inches, for five or fix weeks, to obtain strength for final plant-

ing in June or July.

Let boorcole, and all fummer planted things, have a good watering at the time, and again in a few days, if the weather proves dry; and before winter let them be well earthed up to support the plants from the wind and fnow, that are apt to break them down, or at least, to let them awry; which, when it happens, should be attended to, to fix them upright again; observe this of all other winter greens.

The heads of boorcole may be cut in winter, and the sprouts come full in spring; but the heads should be frost bitten first. The sprouts should only be

topped when gathered, and they will shoot out again

BROCCOLI is of two distinct kinds, the purple, as the white; for the green, &cc. are only varieties from them; of each, there are large and dwarf forts, the latter of which is mostly cultivated. All the fore except the white, generally produce side shoots, as we as a head. The white is called cauliflower broccombecause it resembles a cauliflower much, but is not white. This is not so hardy as the purple, nor is a thought so good; perhaps the green may be esteemed the best. Of the purple there is an early and a late fort; the former is sowed to come in at autumn, and the

latter in spring.

The first day of April is a good general time to for for the autumn crop, (though some do it sooner) and the last day of April for the spring crop. A little white may be fown with the early autumn purple. But will be very proper to fow again a fortnight after each and at the end of May, for late fpring use; which though they produce small heads, will be very accept Some gardeners fow in June, or even the beginning of July. Do it in open ground, and fee that the young plants are thinned, when quite fmall, that the may not be drawn up weak; and prick them out when they have got fix leaves, to fix inches distance, where having grown to a proper robust fize, (as about July) let them be planted out at two feet, or a little more, asunder. The autumn fort should be planted towards a warm wall, left it come not in at the time. Broccoli requires a rich and dry foil; yet watering, in a dry time, is necessary to help their heads to swell, and for ward them. Stir the ground about the plants occasionally, and keep them well earthed up. The best broccon feed comes immediately from Italy, whence we first had it; but it degenerates.

BRUSSELS SPROUTS are winter greens, growing much like boorcole, and by some preferred as more deli-

ate eating; but they are not so hardy or productive. Their culture is the fame as boorcole, only they may be

from CABBAGE, there is a confiderable variety of, as to avour, fize, time of coming in, and hardiness. Some re for the use of the table, and others for cattle, though he latter are very sweet before they get solid. The arly dwarf, early Yorkshire, and early Russian, are the hief forts for spring use, and the early and late sugarant as excellent for summer and autumn.

In April, the forwardest cabbages may be tied up, (as ettuces are) to affist them to head and whiten; a pracice seldom seen done, but which will certainly be help-

ul: Use wetted bass.

Sow for early spring cabbages about Mid-August; oon after they are up, thin them: in a month, draw he strongest, and prick them out four or five inches wart, where having grown about the fame time, they will be fit to plant for fpring use; or they may be put out any time after, even in winter; for should frost come directly, it will hardly affect them injuriously. Yet it is a good practice to let some remain in the feedbed, at proper distances, where being well earthed up, or in very severe weather covered a little) they will urvive when those set out are cut off. Plants that are thought too rampant towards winter, may be pulled up, and planted in the same place again, (November) and will thus stand the frost better, and not be so likely to run.

Plant cabbages, if in a middling foil, two feet alunder, allowing fix inches more for a rich one: There should, however, always be fome dung dug into the ground; which not only increases their growth, but prepares the foil for future cropping. If they are planted at half the above distances in the rows, taking care to draw every other plant in time for early greens (or coleworts) it is a very good method, as the ground is better occupied, and the plants protect one another. See Cole-

worts.

The late cabbages, or those of summer and autum should be sown early and late in the spring. For early summer uses, sow after Mid-February on a little her or under hand-glasses, on a warm border; the late crops in March, to the end of it; and for the latest the end of April; when the small Russian sort will answer best.

Sow red cabbage feed either about the middle of he gust, or beginning of March; but as there is must more bad feed than good of this vegetable, be as careful of the fort as possible; i.e. such as will be solid, and

a deep colour.

CARROT, there is a little variety of, in colour, for and time of coming in, though not much in taste. We have orange, red, and yellow, but the former is generally preferred. The fort sown for the first crop, whether cold ground, or on a hot-bed, is the early harn-tarral Both this and the late horn-carrot grow short and thick and are therefore proper for heavy, or shallow soils, a the other forts are for light and deep ones.

Sow carrots always in good time, as the feed list long in the ground, and they are, by many perfors, covered early. A few should be fown in a favourable situation, the first tolerable weather in February, digging the ground well and deep for the purpose; for if it is lumpy, the carrots will grow forked, as they will

also if the ground is fresh dunged.

Carret feed should be mixed with dry sand, or earth, rubbing them well together, in order the better to spread it equally in sowing. Use about twice as much sand as seed, and if earth, it were better to be of a different colour from that on which the seed is distributed, that it may be seen.

If early in the month, the new fown beds may be covered with a little haulm, or straw, which will help the feed to germinate, and preserve them from being thrown out of the ground by frost; and this covering should be continued on nights, and taken off by day, when

tum

fize Wi

rall

lies ons,

ed,

be

elp ing

ing

ay,

hen the plants are up; which practice being conthe plants are do, which placetee being coneath nued for some time, will greatly forward, as well as
her eserve, the crop. Some people sow in December and
late anuary, if the weather is mild; but for this, (and
her circumstances in gardening) situation must, in a
easure, govern, and discretion determine: In this
se, cover the ground with straw, as for radishes; the, cover the ground with straw, as for radiffies; hich see.

If a hot bed be made for carrots, let it be about two

et and a half thick of dung, and covered with eight ches of fifted mould, as foon as the violent hear is gone f. Sow the feed directly, a full quarter of an inch ep, and if covered with lights, give air sufficient to ep the earth only just warm. A hooped bed to be coered with mats may do for this purpose, but in this ering the two feet of dung may answer better than more; in if the feed is hurried up, they will be too tender for the protection of such a covering, and the plants will in to top, and not bottom well.

Thin the plants from to an inch asunder, and in a

the time again to three inches, in order to grow to a nall fize for use; and if not so wanted, at any rate aw some equally, that those which remain may swell operly: Carrots must have a great share of air, if

overed with glafs.

The principal crop of carrots should be fown early the month of March, or before the end of it, and e foon hoed, or thinned by hand, to a small distance, and a while after to a greater; so that together with being and drawing for use, they should at last stand oil. This may feem too much, but certainly carrots ave, in common, too little room allowed them for taining their proper fize. Let the first hoe be of the readth of three inches, and the second of fix. No onfideration should prevail to let carrots stand too ing before they are properly thinned.

A few late carrots may be fown in April and Ma to draw young in the fummer; and fome in August, stand the winter, for early spring use; but carrots the stand the winter grow hard, and are of very lim worth.

In autumn, let carrots be taken up as soon as the leaves begin to change; for when they continue to long in the ground, they are apt to get worm-eater especially in rich soils. Cut the tops off at an inch and lay them up dry and free from mould, in dry sand a layer of sand, and a layer of carrots. All those the are broken, or cut, should be thrown aside for present spending, as they would decay in the heap, and spread infection to the rest. Those who grow large quantities for cattle, stack them in hovels, &c. with a thick coa of straw, bottom and sides, and particularly on the top In a soil that suits them, carrots turn to good account and are excellent food for all sorts of cattle, and particularly pigs.

early and late fort; though, in fact, there is no difference, only as the feed of that called early is faved from

the forwardest plants.

The time for sowing cauliflowers is rather a nice business, but it is generally settled for the 20th of August a day under or over. It will be prudent, however, to sow again a sew days after, but not earlier, as then they would be apt to form only very little heads, and run up for seed. Let the young plants be timely thinned that they may be strong. Prick them out when the first leaves are about an inch broad. And as caust flowers are tender, they will require to be pricked out in the warmest and driest part of the garden. Some of them should be protected under band-glasses, frames, of boops and mats, shutting up close, and covering the glasses with mats or straw in severe weather: not doing this, however, before the weather makes it necessary.

In

the end of April. If winter should overtake some the latest plants, they may be taken up, when in flow with a ball of earth, and planted or laid in a conservator or a cellar, where they will swell their heads, and safe for a month, or more. All the succession cros except the last, should be planted in a cool part of

garden.

Cauliflowers require a rich foil, and to be kept m during fummer, especially when flowering, waten them well twice a week. If the water were impre nated with fheep or other dung, to the ftrength of abo an ounce of falt to a gallon of water, it would he them in fize, for cauliflowers are greedy feeders. The ground in which they grow can hardly be too full dung; nor need there be any fear as to making the rank: a little falt thrown in the water is, however cleaner, and does away the idea of rankness. they are watered, the earth may be drawn from the stems, and put to again. As soon as the head appear break down one or two of the middle leaves over the to protect from the weather: It preserves them whi and cool, and encreases the fize. This should be pa ticularly practiced with Autumn heads, left wet or for fpoil them.

mon Italian upright, both bollow and folid, with the

giant hollow, and turnip rooted, or celeriac.

For early celery, sow in the last week of Februar or first in March, on a gentle hot bed, or in a wan rich border, under a hand-glass, or not. When cult vated so early, it is apt to run, but if only a few plan stand tolerably, it is worth while to try, and even whe in a pipy state it does for soups. Sow thin, cover and keep the earth moist; for the seed is slow in comin up if dry weather.

For principal crops, fow at Mid-March, and again

Mid-April.

For a few late plants, a little feed may be fown at a beginning and latter end of May; and if the ground covered with a mat, it will help the feed to germinate, keeping the earth cool, and from air: but it must taken off, and the ground lightly watered, as foon as eplants appear. If the weather should be very sunny, and the young plants a little for a few days, by raising emat, or laying some brush wood over.

Prick out the plants in moist weather (if possible) hen two or three inches high, at three or four afunder. Vater them every other day for a week if dry wea-

er.

Plant celery when fix inches high, in trenches a yard frant, and fix inches from one another. In a light il, the trenches may be somewhat deeper; but genelly near a spade's depth is proper, and a spade's width, reping the walls firm and upright. Shorten long roots dhigh tops, and push off small side shoots.

If the foil is not very good, dig in a little well-rotted ing at bottom; but the celery will be founder and reeter without dung, so that a little fresh earth were uter; and though the plants will not come up so tge, they will be hardier to resist frost. The later at celery is planted out, the shallower the trenches

ould be.

Water celery at planting as at pricking out, and occamally afterwards in very dry weather, for it likes a oist foil, and will not grow-large and tender in a dry

Earth up the plants frequently (as suppose every eek or ten days, in a growing season) a little at a ne, in order to blanch them, by which they become sip, sweet, and tender: The celery gets tough and nk, when this business is let alone too long. In earth-g up, it is a good way to gather the plants close (but refully) with the left hand, using a trowel, or small ade.

In severe frest, lay some long, dry, litter over the ps, which remove when the frost goes. In prospect L

Celeriac requires a rich foil, and should have frequent watering to have fine tender roots. Plant in trenche about three inches deep, and earth up, (only once when the plants are about three parts grown, to for inches height. This species is hardier than the other and holds longer in spring; therefore, those who like the solid root should cultivate it.

The feed of celery, (in default of plants) if bruie answers very well to give soup a flavour of it. Park

feed, &c. may be used in the same way.

CHARDON is a gigantic vegetable of the article kind, (now feldom cultivated) used sometimes in sallad but chiefly in foups, or stewed, &c. Sow about the middle of March, and end of April, in trenches, for feet, or more, afunder, a foot wide, and fix inche Drop the feed (which will be near a mon coming up) a few inches asunder, and thin them at la to the distance of from three to four feet. They mu be watered in a dry time. Those plants that are draw may be taken up with balls of earth about them, a planted in trenched rows as celery, at the above diffand and the rows five feet from one another. The leave only of this plant are used, after they are blanched which is done by earthing two thirds of their length when about three or four feet high, tying neat has bands first close round them, to within a foot of the top; i. e. blanch when they are full grown, in August and September, and in about fix weeks they will be for use. In these months it will be well to water the regularly, in dry weather, to prevent their feeding. frost cover the tops with straw: It will assist the bland ing to lay straw, or offal hay, close round them who tied. This plant is biennial here, but perennial its native climate, Spain, &c.

CHOU DE MILAN is of the boorcole kind, and propagated like it, but the plants should be put out at a year as funder. This is a very good winter green, and should be put out at a year as a sure of the long.

onger than any other at spring before it shows for

ed, and is then in its highest perfection.

COLEWORT is a very hardy, small, open headed reen, fown in July, or early in August, for winter and oring use. But instead of the true colewort, (a coarse egetable) it is common to fow the early fort of cabages as an agreeable substitute, to be eat in their open ate. The sweetest, however, is the large sugar-loaf brt, fown about Midsummer, which frequently stands he winter:

These plants should be put out for use at from eight twelve inches afunder, according to the fort as to

ze, though some gardeners plant closer.
Coleworts are seldom cultivated otherwise than for pinter and spring use; but all the year it were well for he garden to supply them, as they are, what may be ruly esteemed, choice greens. With this view, fow abbage feed of some fort every month.

CUCUMBER has several shades of difference in it, rifing from culture and accident; but the common and nore diffinct green forts of it, are the short and the long rickly, the clufter, the early African, and the Turkey. here are also a white short prickly, and a white

Turkey fort; but both are idle bearers.

The early nature of a cucumber is the principal bject with gardeners, for as much skill and care is percised to produce forward ones, it is a great drawack to have fown feed not of the forwardest kind. If the feed called early, there is no doubt much differnce: How material a thing it is to improve the breed, nd to be afcertained of the quality of feed for early rops, is therefore evident.

The principal crop of cucumbers should be the long rickly, which is preferable, on the whole, to any other. The Turkey grows strait, long, and large; but quality certainly before quantity, and the cucumber that eats Typest is the best. In this respect the Dutch, or white bort prickly, (little as it is cultivated) is, perhaps, even before

pole

lipe piec

an e

belo

of th

before the justly admired long prickly, and has fewe feeds: It has an evident difference in taste, and is mostly liked. The early African is a very favourite cucumber with some gardeners.

Seed should never be saved, except from spiny, hand some cucumbers. See, Of raising Cucumbers in the

there are three forts, the curled green and white, and the plain, or broad leaved. The plain, or Batavian endive, is but little used in sallads, as the curled is so much preserable, though cooks preser it for stewing. The green is the hardiest, and therefore the late sowings should be all of this sort.

Sow endine at three several times, between the middle of May, and the middle of July, at equal intervals. Some of the first may, perhaps, run for seed; but ye a little should be then sown; as also at the beginning of August for late use. Scatter the seeds thin, and do not suffer them to grow in clusters to become weak. When the plants are about three inches high, plant them out in an open situation a foot asunder, watering them at the time, and twice or thrice aften, till they have taken root. The same sowing will make several crops, drawing the strongest first, and in a week after more. The best heads are produced from robust plant mover moved, and which have been well watered in a dry time. Endive should have a rich soil.

Those planted out after Michaelmas should be or water borders; but if long after, (as towards winter the method of planting is thus, which blanches at the same time: Draw earth to an high ridge, under a sunny wall, and taking up carefully some full grown endire in a dry state, gather the leaves up close, without breaking, tie them neatly with bass, and put them close together, sideways; i. e. horizontally, in the ridge, almost to the top of the leaves. If any suspicion of we are them, hang the plants up by the roots, in some covered.

overed, shady, airy place, for a day or fo. In severe

reather lay straw over all.

Endive in open ground should be protected from harp frost by peas haulm, or other dry litter. Some may be planted in frames, or under hand-glaffes, giving lenty of air, or in a fhed, or hovel, open towards the

in, either in the upright, or ridged way.

The blanching of endive in open ground is thus: Gather up the leaves (being dry) when nearly of a full rown fize, and tie them regularly, and carefully round, rom the middle upwards, moderately close, with bafs, nd earth them up to the middle, if the foil is light nd dry, but not otherwise. In two or three weeks, he blanching is effected, after which the endive must oon be used, or it will rot, especially if much wet omes. The object of blanching is to take away the leter taste of the endive, and to make it crisp and tenmay come in proper succession. See Succery (or wild indive) next fection.

GARLICK is used for both culinary and medicinal urposes. The cloves should be planted in autumn, or arly in fpring, in rows fix or eight inches afunder, hree deep, and fix from one another in the rows, preerring a light dry soil. If the leaves are tied up in mots in June, it will prevent their spindling for feed, and help their bulbs to swell. Take them up towards. utumn, when their leaves turn yellow; keep them in

ags, or hang them up in a dry place.

GOURD, SQUASH, and CALABASH, as of one family ;

ee PUMPION, the culture being the fame.

HORSE-RADISH is variously used for culinary purposes: when scraped fine, it is a good addition to fallads, specially in the colder seasons. Propagate crowns, on pieces of the root from one to two inches long, having: n eye or two; fet them from nine to twelve inches below the furface of the ground, (according to the nature of the foil, as heavy or light) by digging a trench, and

covering.

covering them over, or by making holes with a dibble; this should be the work of February, or October, and the soil must not only be deep, but rich, or the roots will weak.

This root will grow finer, and be more conveniently dug, to have the rows two feet, and the fets one for assunder in them, though a less distance is the more common practice. Where there is plenty of ground, however, it is not worth while to be cramped, and the first year of planting the ground may be cropped with any early things. The roots will not be fit for use the first year; but the second they come strong and warm. Take them up carefully, regularly moving the early away, and cut off close to the stool, from whence see heads will spring.

New plantations of horse-radish should be made about every fifth year; old ones should be cleared from the straggling side shoots, in order to keep the rows

open, but take them up deeply.

JERUSALEM ARTICHOKE is cultivated for the row (which eats like artichoke bottoms) and it is an ornamental plant, very like the perennial fun-flower, with which it classes, but taller. Propagate in March, by planting cuttings of its root, as potatoes. The root is red, and full of indented eyes, every one of which is sure to grow. Where it has been once planted, it must be carefully dug up, or it will not easily be got rid of Any poor ordinary spot of spare ground will do for it. Preserve the roots in dry sand, when they can be so longer preserved in the ground, immediately dug from which they are much best.

KIDNEY BEAN we have two kinds of, dwarfs and runners, each of which has a rather numerous variety. Both forts have their admirers, but the dwarf fort are more generally esteemed, and more conveniently

cultivated.

Of the variety in the dwarf beans, some come earlied than others; but there is a difference in opinions which

ons,

hick

which is the best, as to earliness and quality. The ellow and the black are, perhaps, as forward as any. The early white is not long behind, and is of superior layour, but not so hardy as the yellow and black, and ome others. The white may therefore be the second crop. The dwarf forts come in quicker than the runners. For the principal crop, the Battersea and Canterbury beans are mostly used by the market gardeners, being good and prolific.

Of the runners, or climbing fort, the common fearlet, and the white Dutch, are generally preferred, and when mixed together, their blossoms make an agreeable how, and bear a long time, if the beans are gathered

freh constantly as they get fit for use.

The dwarf forts of this vegetable may be had most months in the year, by the united means of open culture, hot-beds, and hot-houses. In cold ground they are sometimes sown, close under a south wall, towards the end of a dry March; but April is soon enough; for if they get above ground without rotting, (as the seed is apt to do, when the ground is long wet) a little frost will cut them off. It is a good way to sow again in about a week, lest the first should fail to come up.

The latter end of March, however, if some are sown in a warm border, in patches, and covered with hand-glasses, they will do very well. Or an early crop may be produced by raising the beans, at this time, on a gentle hot-bed, and planting them out, when two or three inches high, under glasses, in patches of sour or sive, and near two seet as under. If the beans are raised in small pots, three or sour in each, they may be turned out whole, with great advantage, as kidney beans do not always bear transplanting well; and they may be covered on nights with hand-glasses, garden pots, &c.

When these forwarded beans are planted in rows singly, let it be under a warm wall, and not (if it can be avoided) till the end of April, or beginning of May; and

protect them awhile at first, on cold nights, with mat

As to the hot-bed culture of kidney beans, if any are attempted to be brought to fruit on heat, let them be raised, towards the end of February, upon one gentle bed, (or in pots, at the back of a cucumber frame) and planted out in another, in rows fifteen inches a-pan, and at four inches in the rows; for nearer they will not fruit well. The bed may be about two and a half feet thick, and must have on it seven or eight inches of

fafely be given them. Line the bed before the heat is quite gone, to preserve and forward them. The son most used for forcing in bot-houses is a reddish speckled one; but the early white is fittest for forcing in hot-beds, as of lower growth: The early yellow and black may

do.

The common culture of the dwarf bean, in the proper feafon, and open ground, is to fow them an inch or an inch and a half deep, three afunder, and two feet, or a little more, to a yard between the rows, according to the fize of the feed, for some forts require more room than others. Let them be earthed up as they proceed in growth; and to have a fuccession, sow every three weeks; remembering that a crop produces more, and lasts longer, the oftener the beans are gathered: It is proper, therefore, to do it constantly whilst young and good, even if not wanted.

The last crop should be under a warm wall, and may be sown as late as the middle, or end of July; and if very dry weather, let the beans for this, and the June crop, be soaked about twelve hours in milk and water, and the drills watered, in order to forward their germination, and bring them more certainly and regularly up. It is a good way to prepare the seed for high summer, by laying it in damp mould till it begins to chit, and then planting it in watered drills. In a course of dry

warm weather, kidney beans should be watered, espe-

cially while young.

The culture of runners is to fow them near two-inches deep, four or five afunder, and the rows four of five feet apart. They will require tall brushy sticks to climb upon; but they may be sown in patches of pan, about fifteen inches diameter, placing the beans five of fix inches afunder, in the circumference, and fixing a pole in the middle for them to run upon. The end of April, or beginning of Moy, is soon enough to put the climbing forts into the ground; and two more fowings. at a month between each, will go through the feafon; i. e. till frost comes.

If feed is faved, let it be only from some of the first beans of the principal crop, for all late formed feeds, and particularly of the kidney bean, are not near fo good as the early ones, often failing or producing weak plants,

and late ill-tasted fruit.

LEEK we have a narrow and a broad leaved fort of, the latter of which is the one generally cultivated. The leek requires a good foil, and open fituation. There is

Sow in February, if the weather is tolerable, or at the beginning of March. Thin in April to three inches afunder, and plant them out the first moist weather after Midfummer, in rows near a foot apart, and at fix inches in the rows; though if the ground be very tich, and the leeks forward, a little more may be allowed b advantage. Trim the tops, and ends of the roots; and it is a good way (if the foil is not heavy) to plant with a dibble, two or three inches in the ground, in order whiten the heads; but to this end some have planted eeks in trenches, and earthed them up high, with a ight foil, or coarfe fand; at any rate, however, if the Towards winter, or in prospect of frost, leeks may

e taken up, and laid with their roots in fand, or earth, a some conservatory, or cellar. A few may be sown

towards the end of April, or even in May, to stand over

the winter for late spring use.

LETTUCE is a vegetable, of which there is a great variety. The brown Dutch, and the green cabbage lettuces come earliest, and are mostly to be depended upon to stand the winter; though some other sorts will except the filver coss and white coss. The brown and the green Egyptian coss are excellent, being hardy and large, forming close heads; but the latter is earliest. The cabbage lettuce eats moderately well, but is chiefly used in soups, &c. The Silesia lettuce is much admired by some, though at present but little cultivated: There is a brown and green sort of it.

For winter and spring use, the hardier sorts are sown in July, August, and September, but chiefly in August when if three sowings are made, the beginning, middle and end of the month, it will generally be found sufficient. They may be sown, however, all September or even at the beginning of October, and it may be stand

when older plants are cut off.

For summer use, the white coss, and any of the others may be sown on warm borders, either in open ground or under hand-glasses, or other cover, in February, and a little constantly every fortnight, or three weeks after chusing cooler ground for them when summer advances Plant them from ten to sourteen inches asunder, according to the fize they attain; it being an error to put lettuces out so near as many do, for it forces them to run for seed, and prevents their growing large: The son called the admirable should be allowed eighteen inches. Lettuces may be pricked out very young; and when three or sour inches high is the best time for planting them.

It is not a common way, but fpring fown lettuces will be forwarder and larger if fown thin, and only thinned out to their proper distance: Those that are drawn may ferve for a second crop. The brown Dutch, great capuchin, the tennis-ball, and button lettuces, do not

run

run up so soon for seed as the other sorts, and are therefore proper for late summer use. To sorward early
spring sown ones, a slight hot-bed may be made, and by
all means ought to be some time in February, if those
that were to have stood the winter are cut off. When
these plants are an inch high, they should be pricked out,
sour inches asunder, upon another gentle hot-bed; and
when they meet, or are sour or sive inches high, draw
every other to plant out in open ground, and let the rest
remain to cabbage.

Winter lettuces, that are forward, are more likely to be destroyed than the smaller, as the wet hangs in them; let them be covered with frames, hand-glasses, or hoops and mats; but covered plants must have a great deal of air at all opportunities. Winter lettuces require a dry soil and situation, and a wet one is helped by planting them on hillocks, which is a method that frequently saves them from rotting: Those in the open ground are often destroyed by grubs lurking about the roots, which

evil should be seen to, if suspected.

To have fine winter lettuces, some of the forwardest may be taken up with balls of earth about them in November, and planted at nine or ten inches distance, on a somewhat strong hot bed, which, as soon as the great heat is certainly over, should be covered with six or seven inches of dry mould for the purpose, but give a little water just about the roots: Line the bed when it gets cool. Lettuces must be well attended to, to give them plenty of air, pick off dead leaves, cover on nights, &c. Frequently stir the surface of the mould, and give water as occasion may dictate. The cabbage lettuce succeeds best in hot-beds.

Tying lettuces with bafs, from the middle upwards, when about three parts grown, will iomewhat help them to whiten and cabbage; but let this business be done carefully. Some gardeners do not think it worth while to practice it; and indeed, right good forts (as to seed) will cabbage themselves, and open ones it is

of little use to; yet this affiftance should be adopted for

the first crop.

Lettuces are sometimes sown thick, to draw young for small fallading; for which purpose, the lap and cabbage lettuces are the properest, as they eat tenderer and sweeter in their infant state: the lap seed is very cheap,

and chiefly the fort used.

MELON there is a variety of, in fize, shape, coat, and colour of the sless. The forts we best succeed with are the musk, (or common oblong ribbed melon) the Roman, the Portugal, and the Cantaleupes in variety, as the common rock, the black, the orange, and the silver. The Roman and Portugal are small, but early. The Cantaleupes are justly the most admired fruit, but are not so good bearers as the others.

The feed brought from the continent (where the melons are much finer than in England) feldom succeeds here. Whoever sows it, must not begin too early, must use more heat, and give less water than is necessary for Denizens. See, Of raising Melons, p. 192.

Onion, we have several sorts, but the Strasburgh (oval shaped) is that mostly cultivated, as it keeps the best. The silver skinned and Spanish (stat shaped) are milder, and therefore by some preferred. The Welch sort does not bulb, and it is rank; but for its being very hardy, is sown thick in August, and suffered to stand so for winter and spring use, as a green substitute for others. At this time, also, some of the Strasburgh may be sown, and perhaps stand the winter in a good situation. The Welch onion is not only hardy, but perennial. They are apt to die down in winter, but the roots shoot again; which, when they begin to do, if earthed over an inch, or so, they will blanch, and eat the milder.

The small silver skinned onion is the fort fittest for summer sallading and pickling. Sow first at the end of March, and to have them young once every three weeks after. Chuse poor ground for the picklers.

The true scallion is got quite out of cultivation, aving given way to the Welch onion; as also to the ther forts, that are made milder scallions of, by plantng early in spring, those that sprout in the house, which quickly grow. Set them in drills fix inches

funder, and two inches apart in the drills.

For the principal crop of onions, fow the Strafburgh or any other, towards the end of February, or foon fter, though any time in March may do, for it is defirable to shun frost: Let the soil be rich. arlieft crops (of course) produce the largest bulbs As oon as they will bear it, (perhaps in five or fix weeks,) et them be thinned either by hoe or hand, to an inch r two apart, and twice afterwards, till each root has full four inches square of ground to grow in.

Onions will transplant when five or fix inches high, aking care to give water immediately, which repeat; but the foil to which they are removed should be rich and well broke. In this way, those whose crops have failed may be supplied from other gardens. If any onion feed is fown, that comes directly from Portugal or Spain, it will be very large the first year, and should have fix inches room allowed them to bulb finely.

Crops of enions should be kept very clean from weeds, and it would be of advantage to water them once or twice a week in dry weather. In July or August, when the leaves begin to dry at the ends, shrink and turn yellow, let them be bent down close to the ground, with the foot, rake, or back of a spade rather hard. In about ten days after, let them be drawn in dry weather, and laid to harden by the fun, turning them every two or three days for a fortnight. House them clean and dry, into neither a warm, nor damp, but clole room; laying them thin, frequently looking them over in the winter to pick decayed ones out, which would damage the rest; But onions are best kept frung and hung up.

The

PARSLEY, broad leaved, as an esculent root, is com monly called Hamburgh parsley, and is eat as carrots Sow it early in March or April, either at broad caft of in drills, and leave the plants fix inches afunder. The roots may be preferved in fand; but it is the practice of some to sow at Midfummer, to draw them young it winter, being best when fresh dug. See parsley, next fection.

PARSNEP is a fweet and valuable root, less cultivated than it deferves, being accounted very nourifly ing. As carrots require a light foil, fo the paring does a strong one. Sow about the end of February or early in March, digging the ground well and deep. If the foil is light, tread the feed in twice over to fasten it in the ground; it comes up in about three weeks. Thin when about two inches high, with fmall hoe, and afterwards with a large one, so as to leave the roots in a good rich foil, a foot afunder, though eight or ten inches will do in light, or indifferent land. Any thing that is to go off quick, may be fown with parfneps, as carrots to draw young, radishes, lettuces, &c. Parsneps are not good till arrived to maturity. These roots are to be taken up, and preferved as carrots; but they may remain longer in the ground, and are feldom hurt by frost, so that some of the roots are commonly left undug till spring; take them then up for use just as they begin to shoot, if they are not wanted for feed; when they will keep good in fand till mid April.

PEA, we have a confiderable garden variety of, arifing from the fize, time of coming in, colour of flower and fruit, and somewhat in taste. The principal distinction is made, as to early and late peas, so that if the earliest pea is fown at the same time with one of the latest, there will be three weeks difference in their bearing, and a fortnight is usually reckoned

between the common hotspur and marrowfat.

The early frame pea (which is that forced in hot beds, &c.) may be fown under a warm wall at the middle, or rather at the latter end of October, or beginning of November, and being kept regularly earthed up, will commonly furvive the winter, and produce peas by the end of May: Do it in short rows, a yard assunder, at right angles with the wall, or rather inclining a point to the east, to catch the first sun.

The frame pea is not a good bearer, either in the fize, or number of its pods, and therefore the hotspurs being hardier and more prolific, are sown by many gardeners for their earliest crop, and the difference of coming in is often but a few days. The frame pea, however, takes up less room than the hotspurs, and in this respect best suits a fruit border, which should not be encumbered with tall crops. Fancy will rule in the choice of peas, but the established sorts of the Reading hotspur, and dwarf marrowsats, are excellent for the summer crops.

The frame pea may be fown a quarter of an inch from one another, and the hotspur half; it is common

indeed to fow thicker, but it is not advisable.

Earthing up peas, and particularly the early crops, should be done frequently, a little at a time, in dry weather, beginning when only half an inch high. The early peas should have some haulm, or dry straw laid lightly against, or over them, in hard frosts: but let the covering be immediately moved aside when the weather becomes mild.

Sticking peas is to take place as foon as they begin to vine, (put forth tendrils,) or appear too weak to support themselves against wind. Let the sticks be set strait, neat, and full; and by all means high enough for the sorts; allowing sticks of three seet above ground for the frame pea, near sive for the hotspur, near six for the dwarf marrowsat, and seven or eight for the larger sorts. If short of wood, sticking only the S. or W. side of the rows may do, if the wind does

of

re

not set very contrary. Some people sow double row of peas at ten inches or a foot asunder, and set slick only in the middle, earthing the peas towards them. Peas that are to grow without sticks, may be sown, the smaller sorts at two, and the larger at three sea asunder.

The beginning of December, more peas may be fown, and towards the end of January, or the beginning of February, in order to have a full supply at the first of the season: The earliest opportunity in the new year should be taken, if those sown before have been cut off, or greatly injured. Peas sown at the begining of February are often not a week behind those of November. Peas sown in the winter months in cold wet soils, may have some coarse sand dug in the drills, to preserve them from rotting, and otherwise help them; some also may be strewed over them.

To have a full fuccession, peas should be fown every three weeks in spring, and every fortnight in summer; which may be continued till the middle of July, when if some hotspurs are sown in a sheltered and sunny situation, they may answer.

The late, and large forts of peas, as the marrowfat, Moratto, American, &c. should be first sown towards the end of February, and not sooner, lest they rot.

The dwarf marrowfats may be laid in the drills half an inch asunder, the large marrowfats three quarters, the Moratto an inch, and the American two inches, and each fort covered two inches. The Leadman's dwarf pea, for it's small size, is admired at genteel tables, and is sweet and fruitful; but rather longer in coming in than the usual late sorts: It escapes the milder better than other peas, and therefore is proper for the latest crops in open ground; It requires sticks only from two to three seet high, and may be sown thicker than any other pea; and till Midsummer. On the same day that hotspurs are sown, put in a crop of any

ks

n

of

ny of these late peas, and they will come in proper accession; i. e. ten days or a fortnight after.

To save seed-peas, let none be gathered for eating,

To fave feed-peas, let none be gathered for eating, accept late formed ones; which had better not be left mong the rest, for the reason given in the article

idney bean.

Peas will transplant, and therefore broken rows may be made up, only chuse (if possible) mild and moist weather for the work in March, and shade them with little straw, while they have taken root. If the utumn sown crops were cut off, peas may be sown under hand glasses in January or February, and thus forwarded, planting them out when they have been two or three weeks above ground.

Watering peas in a dry time answers well, and specially when in flower and fruiting. To receive the water there should be ridges drawn towards the

arthing up, forming a gutter on each fide.

If flugs, or other infects attack young peas, strew some lime fresh slacked, or foot along the sides of the rows, so as not immediately to touch the plants, after which give them a watering, and repeat it a day or two. If the peas are still infested, make another application.

Mice must be guarded against as to nutumn and winter sown peas, by immediately setting traps for them, of which a number of the common block ones will be sound to answer best, setting one at about every two yards, with fresh baits every two or three days.

Peas do not like dung, and will be more fruitful in a moderate foil than a rich one, except the rouncivals, of which we have a white, green, grey, and blue fort.

Stopping peas (i. e. cropping the leading shoot) is practised by some gardeners, to promote fruitfulness and maturity: This is a reasonable practice, but chiefly relates to the early crop.

POTATOE is found to be the most useful root that is cultivated; as a substitute for bread, it is most pro-

stably eat without mixture.

The

CT

WS

ne i

m

t

oil,

eav hey

hall

nay

hou

ug r 1

et v

in a

fet

hal

The potatoe raised from seed, changes the form Some are denominated meally, others waxy; i.e. at either of a loose or a firm contexture: The former best adapted for food, as most farinaceous. They are di tinguished again as to shape, into round, oval, an clustered.

Potatoes will grow in any foil, but best in one that is light, yet cool and good, especially a fresh on Season, as well as soil, makes a difference in the goodness, as does the way of boiling them in eating on which the quality of the water has some effect, a indeed it has on all vegetables, and that is the betwater in which they are boiled quickest. The whit potatoes are generally preferred, but some of the m kinds are very good; and the old rough red from Lan cashire, was one of the best ever cultivated. The kidney (oval) shaped forts are most generally approved as boiling or roafting more equally through; an among these, the red nosed kidney (a white potatoe) is

a great favourite; but many good forts there are.

The coarse kinds of potatoes are given to hogs; but ight whether even for them, quality ought not to be presented. ferred to quantity, may be confidered. The clusters American potatoe is reckoned most profitable for cattle botyielding great increase; but the goodness of a potato
as food, is to be estimated by the quantity of flour is produces. The early potatoes are small, and by come the
mon culture are produced in June, when soon after
their tops change yellow, which betokens maturity
They will keep better in the ground (it being summer as
than if taken up.

than if taken up.

The cultivation of potatoes is various, as experimen to take particular notice of each method; and to fast the every thing that might be advanced on this subject. For fets, or cuttings, preser middle sized, well shape and potatoes, and let each piece have one good eye in it to middle, or at the most two. They should be set it glow rows be

. X7

forth ws, eighteen inches afunder in a poor soil, twentyne in a middling, and two seet in a rich one. In the
mer, the sets may be six or seven inches apart, and
the latter eight or nine: The American potatoe
had the latter eight or nine: The American potatoe
had the latter eight or six inches deep, and in a
eth sevy one only three or four. When planted deep,
hey will not need earthing up above once, but when
hallow, two or three times. In a light soil, they
have a light in with a blunt dibble, but in a heavy one
had deep, and first filled with long dung, old thatch,
while the set would be a great advantage, coverng them up in ridges, and drawing mould to them as
hey settle. Cold, moist ground should be divided into
the set of two or three rows each, with sunk alleys
were enach by earthing the rows up from time to time.
In a heavy soil make the rows rather wider than in a
gibt one, that there be a due quantity of mould for
pre arthing.

Early potatoes are procured several ways. On a
attle bot-bed, some may be planted in February, or under
that they do not bear seed. As these potatoes are small,
after they may be planted whole, or rather cut in halves. ws, eighteen inches afunder in a poor foil, twentyforts

they do not bear feed. As these potatoes are small, after they may be planted whole, or rather cut in halves, rity paring off the eyes at the crown where they are thick, mer as it never answers to have many shoots come from a set; whole ones should be planted a foot as funder, and men halves at eight inches.

Look over the stock of early potatoes, and plant to say those first carefully in trenches that have rooted shoots, for they will produce the first fruit, especially if short and brushy. Do not expose them so long to the air as in it to get withered. When up in hot-beds, or under hander the staffs, let them have plenty of air; and in open ground lows be protected from frost by timely earthing up, and occasional

t-l

casional covering with haulm, or straw, which me not be kept on, but upon necessity. As these east potatoes are on a warm border, a little water in a time will forward them, and increase their size. I default of the true early potatoe, sets with good forward shoots of any other fort may be treated as above; he

they will not be fo good.

From Mid-March to Mid-April is the proper time (earlier or later as the foil is dry or moil to plant for the principal crop, though May, or eve June, generally produce an increase worth the of tivation. The roots from late crops should not be used for planting, as they are more liable to the curl Those potatoes growing sickly in a wet soil, are all subject to this defect. Potatoes, being of superficial growth, should be regularly weeded, as long as the can be walked among without treading on the tops.

Ground, designed for a field crop, should be two ploughed, and the first time it should be some week

before the fetting.

In the potatoe counties, they change their forts even third or fourth year; procuring fresh kinds from place farther North, as a means to avoid the curl, which seems to arise chiefly from the tender nature of the potatoe, and admonishes not to be too early in planting

Seedling potatoes are procured by faving the fift thorough ripe pods, (called apples) and either preferving them in very dry fand till spring, or immediately separating them from the pulp, put the seed up quite dry in papers, and occasionally look it over to keep it so. In March, or April, sow the seed half an inch deep, in a light soil, in drills fifteen inches asunder, and thin the plants to six inches. Earth them up as they grow. Dig them as soon as the haulm dies, and carefully preserving them from frost, they will be fit to plant the next spring for table use.

known; but it is often not sufficiently guarded against

time. Let them be brought in clean and dry. If kept in a warm cellar, they may be laid in a room; ving some straw at bottom, and when in prospect frost entering the house, they should be covered

th straw, a foot thick.

Pying (as it is called in some places) is a good thod of preserving potatoes in winter. They are ed on the furface of the ground, in a rigid form, a width and length at pleasure, according to the antity, but commonly about fix feet wide. ne by digging a spit of earth, and laying it round e edge, a foot wide (if turf the better) filling the ace up with straw, and then laying on a course of tatoes, dig earth from the outfide, and lay upon the flearth. Put straw a few inches along the infide ge, then put in more potatoes, and so on, keeping good coat of straw all the way up between the potaes and the mould, which should be about fix inches ick all over; beat it close together, and the form it s in, with the trench all round, will preserve the tatoes dry; and the sharpest frost will hardly affect em; in a fevere time of which, the whole may be wered with straw. In the spring, look over the ock, and break off the shoots of those designed for e table, and repeat this business, to preserve the statoes longer good.

Pumpions being tender, are raised on a moderate t-bed, in April, or May, according to the time defired have fruit at. After the feed has been up a few ys, prick the plants out at four or five inches, or ther put them in small pots, one in each. When a onth old, they may be planted out about four yards under, one of the large forts, or two of the small ies, on a hale of two or three barrows full of hor ing, and about ten inches thick of mould. Cover ith hand-glaffes, or garden pots, or hoops and mats, nights, till Mid-June. On fuch a hole of hot dung ey may be fown in May, under a band-glafs, and

there remain to fruit. Pumpions will do very we fometimes (in favourable feafons and fituations) for in May, on cold ground. The feed should be cover near an inch, and the plants kept earthing up as the grow. When they have shot five or fix feet, pe down the runners a little way in the ground, and ear over, they will strike root. Water well in dry as warm weather. The orange gourd looks very press when trained up a strong pole, spirally, or to a wall.

RADISH is of two kinds, the spindle rooted, and the round, of each of which there is a variety. Of the former we have the early purple, and the early purple, and the early purple spinds and late large topped ones of both some Of the round there are the white, black, and red turner adishes. The white (of which there is a small an large sort) is mostly cultivated, but the others are good; the black grows large, and the red small. The purple sorts, and the small white and red eat the cooled. The order of coming in from the time of sowing is the purple, and the pink spindle sorts, and the turner red; white, and black: The latter is very hardy so winter use; but the coarsest.

For the first crop, the early purple short top may fown the latter ends of October, November, and De cember, (chiefly the last month) in a warm border, an have a chance of furviving the winter, if a little pro tected in frosts by flout flicks, about two inches high fluck floping in the ground, to support mats; or b laying peas haulm, or wheat ftraw, lightly over them which may be an inch or two thick, as the frost is but no longer than it lasts should the covering be or The first open weather in January and February for again, and in these months, and the preceding on cover the fowing over with some straw, and it wi help to fetch the feeds up, and preserve them from being thrown out of the ground by frost, as also from birds. As soon as they begin to appear, let them b uncovered, to harden them to the air, if the weather low

not too severe. Thin these radishes to an inch and half, or two inches asunder, though some gardeners them grow thicker. Radishes sown in any of the old months (being on borders) lay the ground a little

oping to the fun.

A hot-bed is frequently used for radishes about Christus, or in January and February, which must not be o warm a one, as it would hurry the feed up, and ake them grow all top, and come to nothing. Two et thick of dung is sufficient, on which seven or eight iches of light well broke or fifted mould should be ut on, and the feed immediately fown on the furface, rather thick) and covered half an inch, giving the hole a gentle pressure; for feeds will grow better then the earth is somewhat firm about them. Thin he plants to an inch afunder, before they begin to raw one another up weak; if wider it were better, ut room in a hot bed is precious. Hot-bed radifhes, nder glass, must have plenty of air, for though covered, re not to be thut down close on nights, except severity f frost demand it. In lieu of frames, a hot-bed of adishes may, in February, or after, be hooped, and overed with mats on nights, and in bad weather; and this way, indeed, they generally succeed best. Line orward beds, when the heat declines, that they may roceed in growth, without check or interruption.

Repeat sowing of radishes every three weeks in spring, and fortnight in summer; in cooler ground as the eason advances. In dry weather water. Allow three aches distance to those sown after February, or rather more for the large topped sorts. The turnep kind may now be sown; yet their best season is to come in ster Michaelmas; the small white and red for summer, and the large white and black for autumn and winter, which will often continue good to spring: In prospect of severe weather, some of these may be taken up, and preserved in sand, having first cut the tops off.

Thin the small turnep forts to four inches distance and the large to fix or eight: Sow the two last forts in June, July, and August. In August, or September, son also some of the other forts of radishes, for winter ut Turnep radishes are rarely fown on hot-beds; but the fmall red fort will be found an agreeable early crop, an

may stand as thick as the spindle rooted kinds.

The ground should be well dug for radishes, especially the long rooted forts, and the feed carefully covered full half inch, leaving none on the top (if possible) lure birds, which frequently do much mischief a the crop. It is a troublesome mode, but radishes when drilled are fafer, and being thinned in the rows by hand they come fine. Make the drills for the tap roote forts, from two to three inches afunder, but for the round wider. It is also a good method to sow radishe on beds four feet wide, and the mould being made fin on the top, beat the feeds in with the teeth of a wooder rake till none appear, and then lightly draw the bad of the rake over, to fill up the holes; or, having fow the bed, cover with mould from the alleys, or eart previously drawn aside.

A fprinkle of radish seed may be frequently sown among other crops, as spinach; and the ground a foring that is defigned for cauliflowers, may very pro perly be fown with them, just before the plants are to

be fet out, or between rows of beans.

Draw the roots for use in a regular thinning way and those that are left will become the larger for it.

Radishes are sometimes sown thick for eating, while very young in the feed leaf, with other small fallading

SALSAFY, though but little cultivated, is a useful vegetable. Its young shoots are eat as apparagus fpring, and its long white roots in autumn and winter as carrots, fome of which are taken up, and preferve in fand for winter use. Those left in the ground ma be dug up occasionally, or left to produce shoots for spring, or may stand for seed. Sow them early March XY.

March, in drills ten inches afunder, and thin the plants ofix. Let the foil be good, and two feet deep if pofible.

SAVOY is a cabbage, peculiarly adapted for late utumn, winter, and spring use, as frost improves it, naking it tenderer and sweeter than before. The orts are green and yellow; the former mostly culti-

ated, as it looks best at table.

If favoys are defired forward, fow a little in a warm order in February, or under a hand-glass; but a sowing March, and another in April, in an open fituation, fufficient. Thin the feed bed in time, that the lants may be straight and robust; and when about three iches high, prick them out at five or fix inches difance, where let them grow to a proper fize, (as in fune or July) to plant out at two feet apart, or a little hore, in a rich foil. Chuse moist weather for this ork, if possible, and give some water. Earth them. p as they grow.

Sprouts of favoys are delicate eating spring greens, nd therefore if the ground is wanted where the stalks row, they may be taken up, and laid deep in a trench

or the purpose.

SCORZONERA is a carrot-rooted esculent, and therere requires a deep, and should have a cool soil. Culvate it as falfafy, only let the drills be two or three ches wider, and the plants an inch or two more under.

SEA. CALE, or cabbage, is a vegetable not generally lown, except in Effex, Suffex, and the West of Engnd, but it is much liked by many, and as an early

ring production is valuable.

Its natural place of growth being the fea-beach, it is ident that a fandy foil will fuit it best. Some people ltivate it in almost all sand, which, if it is the natural of the place, is proper, as such surface sand is enwed with good vegetable principles; but when a list made, it should be one half sharp, or drift sand,

and the other half any light rich mould, which me be a little gravelly, or mixed with sea-coal ashes. Son

or plant, either in autumn, or spring.

It is a root that lasts many years, and therefore should be properly planted and managed; either in beds of i like those of asparagus, (the which it precedes for un of four feet and a half wide, and two feet alleys between or in fingle rows of long trenches, which is the bette way. They are best raised from feed, though often from offsets, or pieces of the roots, having two or three eyest

The beds must be trenched, and of a dry loose earth (as faid) to two, or two and a half feet deep; and any fuspicion of wet ever hanging at bottom, lay course of rough gravel or stones there. The plant should be near a foot asunder, kept five or fix inche below the furface, that they may grow through a bod of earth to blanch the sprouts; and they are to be a up four or five inches deep, foon after they appear above ground. In fummer, the ribs of the large leave may be peeled, and cat as afparagus. They will was earthing up from the alleys every year, to keep them the above depth; for which purpose, there should be proper earth in them. It is evidently best to fow, plant, low enough at first, to be prepared for futur earthing up; not to grow too low, however, if there a clay bottom. Sets may be planted at first only the inches deep from their crowns, and earthed up to five fix as they rife: Some do this with fine fitted coal after and the effect may also be attained with the leaves trees laid close round. Little should be cut the fir year, but the fecond do it freely.

The feed should be dropped three or four in a hol half an inch deep, and thinned to one plant, earthing a little as they proceed in growth. When the leave decay in autumn, earth the plants over an inch or two with mould from the alleys. In the fpring, loofenth the earth carefully with the afparagus fork, and at autum quan

the prickly fort to four inches apart, and the fmoot to fix or more, in a rich foil. It in drills fow also thin and cover an inch deep. Some people thin the plant in drills to three inches distance, and draw every other are for use, when those left will grow large, and this may be proper with the smooth spinach; but it is month oil. common not to thin the rows, and to gather, by cut live ting the leaves down low, when more will fpring up again. It is a good way to fow fpinach in beds of four and feet, with alleys, that it may be the more conveniently hir attended and gathered, without trampling the ground farm.—Gardening in this way of narrow beds will, in many attended to the formula to the cases, be found very agreeable.

To have a full fuccession of spinach, sow in fanuar ight and February, and afterwards again in three weeks and then every fortnight, or even oftener, for it presently runs to seed in summer, especially if the plant will grow close. Some people are fond of drilled spinach as it is quickly gathered, and fancied to eat better; but broad cast is commonly reckoned the best way, and id gathering the outside leaves, the plant shoots again eper repeatedly: In spring, however, when the ground is wanted, and the plants are disposed to run, they should be drawn. Spinach will transplant in autumn, and thus bear the best seed.

thus bear the best seed.

TURNEP we have a variety of forts of, for table use differing in colour and shape, earliness and flavour. The ultimost common are the white sorts; but the yellow and record white forms. The small record white Dutch is that mostly cultivated in gardens hey at least for the first crops, though the early stone sort in a very good root. a very good root.

Turneps are fown from March to September, but i June and July for the principal crops. Late cropy re may be fown till Mid-August, but they will produc but little bottoms. Those sown in March will be a to run for feed before they have formed much botton and must be watched to draw them in time. The turne

but i crop oduc be ap otton

urne

thin bough thus cultivated, it can attain but to a very small other was. A bed of this fort must be slight, and have a great other ize. A bed of this fort must be slight, and have a great may eal of air from the very sowing. A moderately light more bil, with little dung, suits turneps best, and they should cut lways have open ground that is well broke. Mix the great with a little fine earth, sow thin, trample close, so and rake lightly: It is a way with some, to sow one ently hird old seed with the new, for the greater certainty and ster misses. Do not neglect to have the crops in time, the early ones to sive or six inches, and the late ones to some ight or nine, though some large forts should have more

the early ones to five or fix inches, and the late ones to huar light or nine, though some large forts should have more leeks listance allowed them.

The When the fly is observed to attack young turneps, it will be proper to stir the ground, and sow again immediately, or to chuse another spot for the purpose.

The Navew (which is much admired by some, and had in it to be the most nourishing sort of turnep) should be again epeatedly sown from March to August, in a moist much it tound; but being a small slender root, need not stand hould rider than five or six inches.

The CABBAGE TURNEP is of two kinds: one apples hove ground, and the other in it. This vegetable is

bove ground, and the other in it. This vegetable is metimes used young for the table; but it is chiefly the ultivated for cattle. Sow it in May, or June, for utumn use, or in June, or July, for the spring: They share very hardy. If sown in a garden, and pricked out, redens hey may be transplanted in fields, the first moist weasort her after a crop of oats, or barley, at half a yard in a cor, or near two feet in a rich soil; and if the ground that is soult the culture gives a fine opportunity to clean it. foul, this culture gives a fine opportunity to clean it, y repeated hoeing.

Balm, and most perennial herbs, should be fresh lanted in beds every third or fourth year; and each ear, in autumn, or foring, have the ground stirred about hem, and dreffed with some fresh earth, or a little well onfumed manure, the plants being previously cut own.

BASIL is a pretty annual, of which we have two orts, the large and the bush: (each having a variety) oth are used as pot-herbs, but chiefly the former. ometimes also this herb (a few of the young leaves) is sed in fallads, and occasionally in medicine. The large rows about a foot high, and the bush but a few inches. leaf, They are both sweet, but the bush most so. It has a elicate round form, and so is cultivated as ornamental, hough its flower is nothing. Both forts are usually fown on a gentle hot-bed, in March or April, and may epricked out in small pots, but will hardly endure the open air till June. The large is the hardiest, and will fame tome up on cold ground, but he backward. They like plant rich foil, and the bush does bett in one full half dung.

BORAGE is a cordial herb, that has its varieties, blue, red, and white flowered, and one with variegated leaves; but the former is that commonly cultivated as a pot-herb, and and its flowers for fallads, and cool tankards. To have ng a it young all the year, let it be fown in spring, summer, and autumn, either in drills, or broad cast. plants to nine inches afunder. It fows itself in autumn,

and likes a dry foil.

Bug Loss pollesses the like cordial virtues with berage, fo that the one may be substituted for the other. Culture is the same.

BURNET is a warm perennial sallad herb, used also in cool tankards, propagated in fpring, or autumn, either by feed, or parting its roots, and planting them a foot

114

asunder. Keep it frequently cut down, that it may constantly furnish young shoots for use.

CAMOMILE is a useful medicinal herb, of which we have fingle and double flowering kinds; and of the latter, a fort with very full flowers. It is propagate by parting its roots, or by its runners, in March, or April, fetting them nine or ten inches afunder. Gathe the flowers in their prime, (as those of all plants should be) before they begin to fade; dry them thinly in the shade for a few days, and preserve them from damp in paper bags. The fingle fort is the strongest, though tor quantity, the double is mostly cultivated: Camomic likes a poor foil.

CAPSICUM is sometimes cultivated for its young pods to pickle; being raised on a gentle hot-bed, or two to bring them forward till June, when (rather about the middle) they may be planted in open ground, about

half a yard asunder. See lists of annuals.

CARAWAY feeds are chiefly medicinal; but being used in cakes, a few plants may have place in the garden. Sow in fpring, in a moist rich foil, and let them have

fix inches fquare to grow in.

CARDUUS BENEDICTUS is fimply medicinal, and is of good repute. Sow it in autumn, either in drills, or broad cast, and thin the plants to nine inches distance, It is annual, and must be cut down to the root for drying,

just as it gets into flower.

CHERVIL is used in fallads, and is also a pot-herb that was formerly in much estimation for its warm nature. Sow it thick in autumn for winter and fpring When fown in fpring, or fummer, it runs quickly to flower. The feed must be slightly covered, and the leaves gathered for use young, cutting it down like parfley, (which it refembles) it springs again.

CIVES are small bulbs, and a fort of mild perennial onion, the leaves of which are cut for fallads, and culinary purposes, at the spring, before onions come in the linary purposes, at the spring, before onions come in the linary purposes, at the spring, before onions come in the linary purposes, at the spring, before onions come in the linary purposes. They will be spring to the line on the linary purposes the line on the linary purposes. from the rooted clusters, and used as onions. They

which are propagated in autumn, or early in the spring, by planting five or fix of the little bulbs in a hole, an inch

oung

two.

gate leep, and eight afunder. A bed of them lasts three or our years.

CLARY (the common garden) ranks as a medicinal hould berb, but it is used also in soups, and is very odorous. on the Sow it in spring, and when two or three inches high, or thin them to this distance. It is biennial, and thereore must be sown every year as parsley is. There are orts of this plant cultivated for ornament, bearing pretty owers. See List of biennials.

CORIANDER is occasionally used in soups and sallads, bout burposes, which its feeds are used in. For culinary uses, but in April, and once a month, or oftener, afterwards, wit in April, and once a month, or oftener, afterwards, no drills fix inches asunder, to have a succession of young lants; and make a principal sowing in August, or Sephave omber, on a warm border. Cover some of it with a same, or it will die in hard weather. If wanted early in the year, sow on a hot-bed, in February or March; or in this last month under hand-glasses.

Corn Sallad (or lamb's lettuce) is a small, warm, wholesome, hardy herb, and for winter and spring use hould be sown in August and September, and again in Subruary and March, and once a month all summer,

herb february and March, and once a month all summer, or it is to be eat quite young. The plants should grow bout three inches distance: This rustic vegetable used the CRESS, there are three sorts of, plain, curled, and particularly with mustard, rate radish are The analysis.

Mid herb, with muftard, rape, radish, &c. The curled mial and broad leaved forts should be thinned to half an ch asunder; but the plain is to be sown thick. The rine urled makes a pretty garnish. In the cold months, is saliad herb (as others) is sown on gentle hot-beds, iving plenty of air; and as the spring gets up, on are sarm borders, or under hand-glasses. The London M 5 market

market gardeners fow it just within the glasses which cover their cauliflower plants, &c. In fummer it should be fown in shady cool ground, and daily watered; or it may be fown in the most sunny situation, if hooped over, and shaded with a mat. Break the mould fine, and draw level shallow drills, and cover only a quarter of an inch. It may, however, be form at broad cast, the ground being first raked very smooth and the feed just covered with fine fifted mould. it be fown (on an average) once a week, and cut young. If that which is fown in open ground, at an early feafon, be covered with a mar, it will forward the germination. The American cress is much like water cress, only more bitter. It answers well as a winter and early spring sallad, being sown in August, at broad cast, or rather thin in drills. The plants being cut, or the outfide leaves pulled off, shoot again.

Drew is a very stomachic herb, whose leaves and seed vessels are put among vegerable pickles, particularly cucumbers, to heighten their relish. The stem, leaves, and seed, are also used in medicine; leaves sometimes in soups and sauces. Sow it either in autumn, or early in the spring, at broad east, or in drills, a foot assunder, thinning the plants to about eight inches. It sheds

feed freely, and comes up at fpring.

Fennel (the common fort) is an hardy perennial herb, of the same family as dill, the uses of which are well known. It may be fown either in spring, or autumn, and the plants ought to be kept near half a yard assunder; or it may be propagated by slips from the roots of old plants. It should be constantly cut down to prevent feeding, which would cover the ground in a troublesome degree. Sweet fennel is an annual, cultivated for its seeds in medicine.

Finochio is a fort of dwarf fennel, very aromatic; the bottom of the thick stalks of which, being earthed up about three weeks, when nearly full grown, five of fix inches to blanch, are used in foups and fallads, or

fliced, and eat alone with oil, vinegar, &c. Sow it thick in March, in drills, about two feet afunder, and repeat the fowing every month till Mid-July, as it pre-Thin the plants to feven or eight fently runs for feed. inches. It likes a dry foil. In a warm fituation fome may be fown in February; the last crop in June must be in a like fituation, and will not be ready before winter; at the approach of which, protect it from frost with dry litter.

Hyssop is used sometimes in a culinary, but more in. a medicinal way. There are white, blue, and red flowered forts of it: but the blue spiked is that commonly cultivated. The parts for culinary purposes are the leaves, and young shoots; and the flower spikes are cut, dried, and preferved for medical uses, for which it is an excellent herb. As hyffop is a woody evergreen perennial, growing about a foot high, it may be planted for an edging of the kitchen garden. It is propagated by feed, and rooted flips, in March, by cuttings in April, or young flips in June, or July. A poor dry, or fandy foil, best suits it. The plants may be nine inches, or a bot afunder, as an edging, but should be near two feet from one another in a bed, as they foon get large.

LAVENDER (the common) is, for its pleafant aromatic fcent, found in most gardens, and makes a neat perennial edging in large ones. It is propagated by cuttings, or young flips, in April and May, fet a few inches afunder, in a fleady fituation, and good foil; and when rooted, planted out where they are to grow. The flips should be occasionally watered, and as a mat would cover a great many, might be shaded when the fun is. hot upon them, for a fortnight or three weeks, to forward their rooting. But though raifed in a good foil, lavender likes a poor and dry one best to abide in. the plants at a foot distance from one another. rich moist soil, they are apt to die in the winter; but in a dry hungry one, they rarely do. luxuriantly they grow, the more likely they are to be

cut off by severe weather.

MARIGOLD has its varieties, and some forts bear very fine double flowers; but the common fingle kind is best as a pot-herb, being most aromatic. All fingle flowers are preferable to the double of the same kind for medicinal, or other uses, as possessing a stronger effence. Sow marigolds in spring, and let plants of the fingle fort stand a foot afunder, but the large double wider. They will grow in any foil, and are in flower most part of the year. The time of gathering them for drying is towards autumn, when they are most plen-Take care that they are not put up in their paper bags raw, or damp, and keep them in a very dry This flower is a valuable ingredient in broths and foups, however it may have got into difuse. It fows itself abundantly, and will bear transplanting about May, so that there will seldom be occasion to sow.

MARJORAM is distinguished into pot, winter, and knotted forts; the two former perennial, and the last annual. They are all occasionally used for culinary purposes, but the knotted is chiefly cultivated as a sweet companion of our flowers. The propagation of it is by parting the roots of the perennial forts in autumn, or pring, and by sowing the annual kind in March, or April, on a warm border, and light dry soil. The annual fort should stand at six inches distance, and the perennial at nine or ten. The knotted fort, if planted in pots, and housed, may be preserved in the winter, cutting down the flower stems. This kind is sometimes used for medicinal purposes, and should be drawn up by the roots, for drying in the shade; or at least with

but little fun.

MINT is a falutary herb, of which we have two forts, the *spear* and the *pepper*; the former for *culinary*, and the latter for *medicinal* purposes. There is a little variety in the *spear*, as broader and narrower leaved,

and also variegated forts, white and yellow, but these

are confidered only as ornamental.

Mint is propagated by pieces of its roots, or rooted flips, in the fpring, fet an inch or two deep, and eight alunder, on beds four feet wide. Cuttings will quickly frike root in any of the fummer months. It delights in a moist soil, and new plantations of it (particularly cuttings) should be well watered in a dry time. is to be had young all winter, and early in spring, by means of a gentle hot-bed, on which it should be set pretty close; and for a succession, make a new plantation every three weeks, as the roots will perish in about that time. Or it may be conveniently planted in pots, and placed in any bed, and so shifted from one to another, if occasion. Do not let this, or any other herb, be badly dried, or preferved, as is too common a cafe. For prefent use, gather only the young leaves and fhoots.

MUSTARD is much used as a sallad herb, gathered quite young, and the white is the garden fort, the black being cultivated in fields for its seeds to make flour of.

It is managed as cress, which see, p. 249.

NASTURTIUM, there is a greater and less fort of, both cultivated for their unripe berries to pickle, their flowers for fallads and garnish, and as a garden ornament; but the large is that chiefly cultivated for culinary purposes. Being climbers, they should have something to lay hold of, as an arbour, or bruth wood, or nailed up with shreds to a wall. They are of free growth, and flower abundantly for a long time, even till the frost comes. Sow an inch deep, in drills, in a light foil, and warm fituation, in April, or fooner, if on a gentle heat, to forward them. It is best to sow in a few small pots, holding each two plants, from which they may be turned out whole (before they get too big) in May; though fometimes they transplant without earth, about the roots, very well. Give them plenty of air while under cover, or they will be drawn up weak.

weak. A fresh, but poor, soil, is better than a rich one, which makes them too rampant, and less fruitful.

See List 8, Sect. 19, and Observation.

The double nasturtium is considered merely as a fine shower, but they are a beautiful garnish. It grows from cuttings: Plant these in pots, in June, and place them on a little heat, and they will soon take root. Or if the pots are plunged in a warm border, and covered elose with a hand-glass, it may be sufficient. Gently water them when the mould gets quite dry. This plant is tender, in winter requiring a stove; yet it shourishes all summer in open ground, slowering most in

a poor foil.

PARSLEY we have a plain and a curled kind of; and though the former is mostly used, yet the latter is equally proper as a pot-herb, and it makes a good garnish: It cannot be mistaken for hemlock, as the plain fometimes There is, however, more of effence in an has been. equal quantity of the plain, than of the curled; but it is only using rather more of the latter, which, if not suffered to feed, will stand three years. Po produce the curled fort very fine, (as for garnish) the plants should be thinned to three or four inches afunder; and it may be fown either at broad cast, or in drills about nine inches afunder, as the common fort is. Parsley is sometimes fown early in autumn, to have it young for the winter and spring; but the usual time is early in spring, and one fowing may be sufficient for the year: Cut it down often to get rid of the old, and young will fpring up. Cutting down parfley should never be omitted about the end of September, that it may be had good through the winter and fpring. This herb will bear transplanting. For Hamburgh parsley, see parsley in the last section, p. 230.

PENNY-ROYAL is a pot and medical herb of the mint species. There is an upright and a trailing fort of it; but the latter is that chiefly used: This is propagated by rooted branches, of which it affords plenty,

paty, as as it spreads fast; and it will grow in the summer months from slips, or cuttings. Set them a foot asunder in spring, or autumn, and in a strong moist soil it will most flourish. If, however, it is suffered to mat thick, it is apt to rot. As this herb is often wanted in winter, let it have a somewhat sheltered situation. If cut for preserving in winter, the time of flowering must be observed, and it must be very carefully dried and kept,

as it is apt to mould.

Purslane is a low growing succulent herb, of a cold and tender nature, used chiefly in summer fallads, but sometimes for culinary purposes. The sorts are the green and golden, but the former is preserred, and is hardiest. This plant will not succeed in the open ground till towards the end of May, and then it must have a warm border. In March, or April, it is sown on a gentle heat; for which purpose the lining of a hot-bed may do. Sow in drills four inches apart, cover a quarter of an inch, and let the soil be light and rich. In dry weather, water it twice or thrice a week. The end of the young shoots only are used, and when cut down it springs again. It is usual to sow it three or sour times in the summer, in cooler places, as the weather gets hot.

RAPE, or coleseed, is fown for a fallad herb, to be eat while in the feed leaf, with mustard and cress; and is to be treated as they are: it is stomachic, and some

persons are fond of it when boiled.

RAMPION is a fallad and culinary root, in but little request. Sow it thin in April and May, and leave the plants at four or five inches distance, for autumn and

winter use: Draw it young.

ROCOMBOLE is a root much like garlick, producing small bulbs at head, as well as root: is chiefly medicinal. The cloves may be planted in autumn or spring, two inches deep, and four asunder. Treat it as garlick, which see. It is sometimes used as a mild substitute for

for garlick. The feeds are eatable as well as the cloves.

ROSEMARY we have the varieties, plain, filver, print and gold striped. The plain is a useful medicinal herb, ut which should be found in every garden. It is propagate gated by suckers, layers, slips, or cuttings, in the spring, a positive fetting the two last where they have not much sun; and when rooted, towards autumn, or in the following he spring, allot the young plants a station rather warm, and sheltered, as rosemary is apt to suffer, or die, in out in fevere winters, especially the variegated.

RUE is a medical plant, propagated in fpring, by feed, flips, or cuttings. It stands many years, but should be prevented feeding, and pruned down occafionally, to keep it in a neat bushy trim, of moderate

height, and strong growth.

SAGE there are several forts of, but the common red is that used chiefly for culinary purposes, and the green both for these, and medicinally for tea, &c. There is a narrow le ved green fort, called tea fage, or fage of virtue; but the broad-leaved green is reckoned by some better, not being so heating, and unpleasant to the taste. The variegated forts of fage are only confidered as ornaments in the flower garden, or fhrubbery. Sage is propagated by flips or cuttings of the last year's shoots, in April or May, chusing those that are short and strong; or of the young shoots in the early part of summer, set in to an inch from the top, and about four inches diftance, in some shady place. These, if they spindle tall in the fummer, should be pinched down (in time) to. about three inches, in order to form bushy heads. They will be well rooted in August, when they should be planted a foot afunder, in a funny and sheltered situation, from the N. and E. that they may stand severe winters, which they will the better do, if the foil is rather poor.

SAMPHIRE is by some greatly esteemed for a pickle, using its leaves, which are sometimes added to sallads, and

the and occasionally used medicinally. It is perennial, and fopagated by parting its roots, or by feed fown in fopagated by parting its roots, or by feed fown in fiver, but yet prefers a fandy, or a gravelly foil: Let it ave plenty of water. Some have found it to do best ing, a pots.

Savory we have a summer and a winter kind of; the former is annual, and the latter perennial; and both rm, reused as medicinal and culinary herbs, but the summer in ort is that mostly cultivated for medicine. The annual appropagated from seed in March or Atril sown thin

as

,

but hord fallow, in drills, eight or nine inches afunder. The perennial is fometimes propagated from feed, but nore usually from rooted slips, or cuttings from the op, in spring, as also from side slips. The annual sort hould grow at six inches distance in the drills, and the evennial be allowed a foot. Summer savory, gathered for drying, is best drawn up by the roots.

SMALLAGE is a fort of wild parsley, found in moist laces, and was formerly much cultivated in gardens, and used in soups and sallads, and medicine, as a warm terb. Sow it in spring as parsley.

SCURVY GRASS (the Dutch, or round leaved) is

Scurvy Grass (the Dutch, or round leaved) is ometimes cultivated in gardens for its excellent mediinal properties. Sow it in autumn, or spring, but best arly in the former. Though it will grow in any foil, thould have a moist one.

SORREL is an acid, perennial plant, much relished y some as a sallad, often used as a pot-berb, and someimes as a medicinal one: Though found common bough in the fields, it is much improved by garden ulture. The round leaved fort, commonly called the Roman, is reckoned the more grateful acid, and enreases in the ground apace. Sorrel is generally proagated by parting its roots, either in spring or autumn, nd if propagated from feed, (which produces the finest lants) it should be fown in March. The plants of the ommon forrel should be fix or eight inches asunder,

and the other a foot, or fifteen inches. Common for rel likes a cool moist foil, but the Roman a dry one Cut it down at the latter end of the year, and cover i over with a little mould, first stirring the foil.

Succory is a fallad, pot, and medicinal herb, but not much cultivated. To be good, it must be wel blanched as endive, of which it is a wild fort. Sowi

in March for autumn and winter ule.

TANSEY is a culinary and medicinal herb, of which besides the common, there are curled leaved, and varie. gated forts; but the former only is proper to be use medicinally. It is personal medicinally. It is perennial, and propagated by rooted sw flips, in spring or autumn, set at eighteen inches distance in beds, four feet and a half wide; and will grow in an foil, or struction foil, or fituation.

TARRAGON is a perennial pot and fallad herb which was formerly much admired for its peculia high warm flavour. It is propagated fometimes from feed, but mostly by rooted, or other slips, fet in spring or autumn, at fix or eight inches distance, and may be by cuttings in the fummer months. The many be dried and the wanted in winter, it may be dried and the beautiful to be the beau as other herbs are, or forced as mint, in order to have ut it green. When the stems begin to run, cut them down, in order to produce young shoots, for the tender tops only are to be used; and that not too freely, as it has a state of the s is an herb that heats much.

THYME is a pot-herb, of which there are commonly former mostly. There is a fort called lemon thyme that is admired for its flavour, and another called film om thyme, which, with the ftriped, are considered rather a merely ornamental. It is best to miss the state of the state forts from feed, though root branches, on account o their trailing nature, may be usually had from old plants Slips will grow, if fet in a light rich foil, in a shad fituation, or kept moist by watering. Loofening the earth

one ear, will produce plenty of rooted branches the next. Wer in the plants should grow at six or eight inches distance. Spropagated from feed, let it be sown thin in March, and covered lightly. Slips are best made in April. Well this herb makes a neat edging when planted close, but is a great impoverisher of the ground. Keep it low.

Tomatum, or love apples, we have red, white, and some some sould be sould be some some sould be some s

Tomatum, or love apples, we have red, white, and thich allow fruited; and of the red and yellow, a cherry-baped fort. The first, or large red, is that commonly used ultivated, and it serves for an ornament in the garden, sooted swell as of use for the table, in a pickle made of the reen fruit, and when red in soups, &c. It is also metimes pickled when red, (i. e. ripe.) At the end of March, or beginning of April, it must be sown in moderate hot-bed; and being soon thinned, let the saliants grow two or three inches high, and be pricked a small pots, to turn into the cold ground towards the ring and of May; or if not long and weak, keep them and of May; or if not long and weak, keep them and of cover a little longer. Give them a sunny situation against a wall, for regular and timely training, and in rows should be three yards assunder. If planted that upon holes of hot dung, it would help their speedy being, and forward them much for ripening their mide that, which in bad seasons they sometimes fail in. They require much water in dry weather.

Wormwood is a useful medicinal herb; and com-

Wormwood is a useful medicinal herb; and comonly non as it is in many places, in others it is not to be met the with wild. Besides the common, there is a Roman wormome wood—both are efficacious; some preferring the one, ome the other. They are commonly raised from sips or a mid cuttings, in any of the summer months, or from seed

own in spring.

mot et o ents nady the

# SECTION XVII.

OF FRUITS.

THERE is a variety (and of some a great one) of each kind of fruit, and the difference of tafter makes it impossible to pronounce upon their particular merits. With respect to fruit, there are provincia prejudices in favour of some, and of apples in particular for that in one county, a fort shall be generally known ave and admired, and in another, not be heard of.

In affifting the young gardener in his choice of the rope principal fruits, only a few forts will be named; such as move have obtained almost an universal credit. It would be to well if the number of some kinds (as in peaches) were reduced; for their multiplicity occasions a great uncertainty, and their shades of distinction are hardly discovered by the best judges. Nurserymen's catalogues surnish large lists.

nish large lists.

Of the same fort of fruit there is often a perceptible difference, owing either jointly or separately to the stock, state of the tree, soil, situation, management, who and season. Bad planting, by cramping the roots, &c. will often induce sickliness, and of course a good plant he and to a real control of the season of t will often induce fickliness, and of courte a good praise made to produce small, ill-flavoured fruit, and thus it will appear to be not itself. So that when the best year method is taken to procure good fruit, (or such that please us) which is by graffing, or inoculating from the late please us) which is by graffing, or inoculating from the late please us have admired the fruit of, our expectations may, in a measure, be disappointed by a variety of circumstances.

varr

or e

OF FRUITS.

NURSERYMEN, it is often faid, are not to be deended upon, for if they have not the fort you want, hey will fend you one they have; and this may someines be the case, as they may think it of little conequence if you have one that is good. But the cafe there is a great confusion in the names of fruit, by mident, ignorance, carelefiness, &c. New titles have een arbitrarily imposed on old fruits that have hapened to vary a little; and distinctions made without difference, of which circumstance Mr. Evelyn comlained in his day, faying, "The discriminating the everal kinds of fruit, by their characteristical notes, from the leaf, taste, colour, and other distinguishing propertular ies, is much wanting." But as Mr. E. observes, the bility for this is only attained by long and critical observation. Dr. Hill (in his Eden, folio) professes to own ave given great affishance in this matter. "Under the section of fruits (says he) we shall give their he section of fruits, (says he) we shall give their

the roper names and descriptions, by which every one will has now by what names to call those he sees." I doubt to another that an intimate acquaintance only can do it.

Disappointment frequently originates with the purcer, baser, who having met with a fruit to his mind, aquires the name, and is told a wrong one, and that, erhaps, of a bad fort; the nurserymen then complying with his order, is blamed. A reduction of the number forts to those in which there is an exident difference.

SE-

with his order, is blamed. A reduction of the number florts, to those in which there is an evident difference, the with more care on the part of those who raise, and those ent, who buy trees, in all respects; and particularly that of reserving the true name seems necessary, therefore, in lant he affair of fruit trees.

The choice of fruit trees should be somewhat governed best y soil and situation; (which has been observed) for that fruit which succeeds in one, will not in another. the later fruit may be planted in light soils than in strong the same some some sorts grow finest in a cool, others in a circumfoil, and some situations are too bleak, either the early or late fruit, though the aspect, and all other circum-

circumstances, may be good. In planting fruit tree particularly those of the wall, much discretion is neces

fary to avoid disappointment.

As fruit trees are so readily purchased, sew people care to raise them; but those who may be dispose this way, will find instructions in the sections nurse and graffing. The purchaser must attend carefully the planting, for which work directions have been given in the sections of the formation of a garden, an that on planting. For the training and pruning fruit trees, ample rules are laid down in the fection rea On pruning: fo that nothing need be faid of their cult vation here, making proper references.

APPLES, as the most useful fruit, it will be propert provide as many trees of as there may be found du room and occasion for; taking all care to procure go forts of the two kinds; i. e. for eating raw, and dressed the and to have a proper assortment of the summer, autumn town

and winter fruits.

For the first season, jenneting, common codlin, may garet apple, and Jummer pearmain. Second, golde pippin, Holland pippen, golden rennet, white calvill and Kentish codlin. Third, nonpareil, golden russe Wheeler's russet, winter pearmain, Kentish pippin, ris and Wheeler's russet, winter pearmain, Kentish pippin, ris and the Joh orts. stone pippin, margille, Norfolk beefing, and the Job orts apple. There are, no doubt, other apples very good ent but, perhaps, these have as much merit as any. Wit break respect to raising, planting, pruning, &c. see pages 30 35, &c. 68, &c. 79, &c. 97, &c. 156,7,60.

The gathering of apples, and other fruit, from stand of ards, is often badly performed, damaging the branche age and breaking the spurs off; let this business, therefore be properly attended to, particularly in young trees good forts. Do not pinch, or bruise, fruit in gathering with

for even the hardy apple may fuffer.

CORNEL; i. e. Cornelian cherry. The fruit used to be by many preserved to make tarts, and a medicine preparation was also made of it, called rob de corni See cherry, list 2, sect. 19.

CHERRY: The forts may be the early May, Manduke, (ripe in June) white, red, and black hearts, bleeding heart, bigeroon, Turkey, tradescants, and morella; which may be added, the yellow Spanish, and white

Swifs, ripe in August.

In gathering cherries, take care not to pull the fruit four off, which is a very common thing. If they are properly ripe, they will part eafy from the tree. So pages 31, 37, 85, 90, 103, 157, 160, 163.

CHESNUT is not a garden fruit, but the manured or Spanish fort, in an open fituation, produces good nut about Michaelmas, and may be kept all winter, if of

vered close from the air. See page 75.

CURRANT, we have a small red and white, with larger of each, called Dutch currants, the Champaign or pale red sort, and the black. There are currant tree with variegated leaves, and a sort with a gooseber leaf. See pages 31, 38, 76, 106, 159, 163.

Fig is a fruit, the forts of which that are mostly planted without doors in England, are the common large blue, early dwarf white, and large white. The first kind is the hardiest; but yet do not always ripen well with us abroad. See pages 29, 30

74, 103, 105, 151, &c.

FILBERD, we have a white and red fort of, and the latter judged most agreeable in slavour. Other number are the Spanish, cob, and hazel in variety. The first a large nut with a thin shell, and the second is a large one with a thick shell, but both are good. There is nut near two inches long, but it does not kernel well See pages 37, 71, 76, 158.

GOOSEBERRY, there are many forts of, arising from their propagation by seed, differing in their time of coming in, size, colour, &c. The large forts of gooseberries (weighing from ten to sisteen penny

weights

XVII

fed t

NECTARINE is much like the peach in all respects only that it is smaller, has a smooth skin, and of sime shesh. The Newington, red Roman, temple, and murn are good sorts, to which the curious, in a good situation, may add the early nutmeg, the late green, of Peterborough, and the white Italian.

In gathering nectarines and peaches, never pinch then to try whether they are ripe; for when so, the touch will discover it, and when thorough ripe (as they should be) they will come from the tree with great ease. So

pages 29, 30, 71, 90, 103, 108, 129, &c.

NUT, see Filberd.

PEACH (in general) succeeds better than the necharine, as to bearing and ripening. There is a great variety of peaches under cultivation in England, but on the Continent the number is much greater. The following may be recommended: The early Ann, earl Newington, early purple, the red and white Magdalant the two mignons, noblesse, admirable, old, or late New ington and Catherine.

Peaches cannot be too ripe, (see nectarine) so the those which drop are by many reckoned the best; and those whose steel adheres to the stone (called pavis are by some thought the more delicious. The noble and admirable part from the stone. See pages 29, 71

90, 103, 105, 129, &c.

PEAR, there is a great variety of, classed into summer autumn, and winter scuits. The summer sorts may be the green chissel, Catharine, Fargonelle, and summer Bonchretian. The autumn, brown buerre, bergamot swan's egg, and dean pear, or St. Michael. The winter St. Germain, cresan, winter bonchretian, colman and chaumontelle. These all come in for eating regularly, the first in July, and the last continues on June. Baking pears, Parkinson's warden, the union, Uvedales St. German, cadillac and black pear of Warcester, good to Midsummer.

are ripe, as when thoroughly so they eat meally, and will not keep well above a day or two; even when gathered as they ought to be, in a week, or less, they will go at the core: They should not, however, be gathered, while they require much force to pull them off. Autumn pears must also not be full ripe at the time of gathering though they will keep longer than those of the summer. Winter pears, on the contrary, should hang as long on the trees as they may, so as to escape frost, which would make them flat in flavour, and not keep we'l. Generally they may hang to the middle of October on sull standards, a week longer on dwarfs, and to the end of the month on walls; but yet not after they are ripe.

The art of gathering, is to give them a lift, so as to press away the stalk, and if ripe they readily part from the tree. Those that will not come off easy, should hang a little longer; for when they come hardily off, they will not be so fit to store, and the violence done at the footstalk may injure the bud there formed

for the next year's fruit.

Let the pears be quite dry when pulled, and in handling avoid pinching the fruit, or in any way (in the least) bruifing it, as those which are hurt not only decay themselves, but presently spread infection to those near them: When suspected to be bruised, let them be carefully kept from others, and used first. Gather in shallow baskets, and lay them in gently.

House pears in a dry airy room, at first thinly for a few days, and then put them in heaps to sweat; in order to which, a blanket thrown over them will help. The fermentation must be watched, and when it seems to have passed the height of sweating, wipe the fruit quite dry with fine slannel, or clean soft linen, and

fore them:

The storing is thus: Those to be used first, lay by singly on shelves, or on the stoor, in a dry southern N 2

room, on clean dry mofs, or sweet dry straw, so as not to touch one another. Some, or all the rest, may be stored as directed for apples; for they will thus keep very well, having first laid a fortnight fingly, and then nicely culled. But the most superior way is, to pack in large earthen, or China jars, with very dry long moss at the bottom, fides, and also between them, if it might be. Press a coat of moss on the top, and then stop the mouth close with cork, or otherwise, which should be rofmed over, with about a twentieth part of bees-wax in it. As the object is effectually to keep out air, (the cause of putrefaction) the jars, if earthen, may be fet on dry fand, which put also between, round, and over them, to a foot thick on the top. In all close storing, observe, there should be no doubt of the foundness of the fruit. Guard in time from frost those that lie open. Jars of fruit must be soon used after unsealing. See pages 31, 37, 44, 71, 74, 82, 89, 90, 95, &c. 103, 153, 160.

Plum, of the many forts the following are good: Green and blue gage, Fotheringham, white and blue perdrigon, drop d'or, la roche Corbon, la royal, and St. Catharine. The imperial, or red magnum bonum, and white magnum bonum, are chiefly used in tarts, and for sweetmeats, as is the Wentworth. The early white primordian (not a choice fruit) is valuable for its coming in the beginning of July; and the imperatrice for not coming in till October. Damson and bullace plum, black and white, very late in the season, for tarts, and a fine acid preserve. See pages 31, 37, 71, 74, 82, 90, 103,

158, and 160.

Quince, we have the common apple, and pear shaped, and Portugal pear shaped. This fruit cannot be eat raw, but for marmelade, and baked in pies, &c. the housewife finds it useful. The Portugal is mostly esteemed. Quinces may hang till November. The ripe ones only are of value, which after sweating a few days,

the

ftly

he

ew

ys,

days, must be laid fingly (at some distance from one another) on a shelf. See pages 37, 74, 103.

RASPBERRY, the kinds are red and white, and of each a twice bearing fort, i.e. producing fruit in fummer and autumn. Of the red there is a prickly wooded fort, and a smooth one, called the cane, and sometimes the reed raspberry; and the large Antwerp, of a yellow white, sometimes called the Middleton Rasp.

Gather this fruit carefully, and not long before wanted; lay no great quantity together. Raspberries presently lose their flavour, and tend to decay. See

pages 38, 55, 77, 106, 164.

SERVICE, (sweet) or sorb apple, is rarely cultivated for fruit, as it requires a warmer climate than England to ripen it. In fact, it never ripens on the tree. It is gathered late in autumn, in a very austere state, and laid by on straw to decay, when in about a month it becomes agreeable to eat. The trees are hardy, and the curious of the plant them, merely for the singularity of their leaves and fruit. This tree is sometimes trained, on a wall, or espalier, as pears. There is a variety, as the apple, the pear, shaped, &c. See lists of trees, 1, 2, Seet. 19.

STRAWBERRY: Of this fine flavoured fruit, beautiful and fragrant, we have the following forts: Red, white, and green wood; red and white Alpine: scarlet; Carolina; hauthoy; red and green pine-apple; Chilis, of forts; with some seminal varieties, as several of the hauthoy, and one in particular of the Carolina, called the pink-fleshed strawberry. There is also a strawberry with one leaf, a variety of the wood and prolific.

Gather strawberries regularly as they ripen, with a bit of their stalk, and never lay many together to press upon one another. The frether they are, the finer cating: for this fruit, as the raspberry, is quite naughtwhen stale. See pages 38, 51, 55, 77, 111, 165.

WALKUT, there are several sorts of, as early and late, small and large, thick and thin shelled, &cc. Two N 3 only

foci the the are Of

or sho wa per 59

only need be named, the early oval thin shelled, and the common round, or royal walnut. All the others seem to be only seminal variations from the last, which is justly reckoned the best fruit. Procure trees from seven to ten years old, as they seldom bear till about twenty years of age. See pages 76, 103.

# SECTION XVIII.

### OF FLOWERS.

Flowers, the fole luxury which Nature knew, In Eden's pure and guiltless garden grew; Gay without toil, and lovely without art, They sprung to cheer the sense, and glad the heart.

BARBAULD.

RLOWERS, as to their cultivation, are classed into annuals, biennials, and perennials. Annuals are those that are sown and slower, and generally die within a year. Biennials are those that are sown one year, and slower and generally die the next; though some of these, by sowing early, and forwarding by a little heat, will blow the same year. Perennials are those that do not slower the year they are sown, but the next, and continue to live years afterwards, some sewer, some more: Of this class there is a great variety, sperhaps sifty to one of the last, mostly sibrous rooted, some sleshy, some bulbous, and some tuberous, &c. Most of the perennials are annual in their stalks, which die down

the ground in winter, and fresh shoots rise in the bring. But, strictly speaking, all of each class are not nnual, biennial, and perennial; for some of the annuals. ome (though more weakly) a second, or a third year, s Chinese holyhock, and Indian pink, and a few others, (which die abroad) would live through the winter if housed. Of the biennials, the same may be said of the lack July-flower, Sweet William, and wall-flower; only the former of these plants does not always live through the winter. All are to be fown, or propagated, as they are classed, in order to have a certain and fine blow. Of the perennials, some do not flower well above three or four years, as the holyhock, &c. for which a fowing hould of course take place the year before they are. wanted: A few may also go off the second year, having perfected only one blow. See pages 41, 42, 55, 56, 59, 64, 65, 69, 110.

The incense of the garden's breath, that sheds
This balmy sweetness.———

To the fmell
How grateful, nor less pleasing to the eye
The bloom of opening flowers.—Kind Nature here
In nice proportion all her favours deals;
Those gales around the blissful garden pours,
Neither too strong the organs to oppress,
Nor yet so faint the senses to elude.

See in what various tints the flowery tribes
Their feveral beauties flew, and court the eye
With new delight, distinguish'd each from each
By different hues—how wise the bounteous hand
Of that indulgent power! tho' perfect all
His works, who yet on all the charms bestows
Of novelty to shew 'em still more fair.

#### I. OF ANNUALS.

Annual flowers are usually divided into three classes i. e. tender, less tender, and hardy.

In the lift, fection 19th, the tender annuals are marked 1, the less tender 2, and the unmarked are

To this list of flowers might be added others, and fome possibly that are pretty; but many of annuals introduced for variety's sake in large gardens, plantations, &c. are weed-like, dull, and rambling; and perhaps a sew among those here mentioned may not be sufficiently ornamental (as, for instance, the whites, where there are other colours of the same flower) to give general satisfaction; for a gay appearance is certainly the first object in the cultivation of flowers to adorn our walks. There are rare plants, and others admirable in their structure and properties, which make no shew; but these are rather subjects for the curious botanist, and he will deservedly think them worthy of a place in his garden.

Some flowers are both beautiful and fragrant; but many have only one of these properties to recommend them. Some are cultivated chiefly for the beauty or elegance of their leaf, as the tricolor, ice plant, palma christi, and the curled mallow; and some that bear pretty and sweet flowers, are meanly surnished with leaves, as the yellow sultan. Others obtain a place in the garden, neither for fragrance, or flower, or leaf; but merely for the singularity of the fruit, or seed vessel, as the egg plant, snails, caterpillars, hedge hogs, horns, and others.

In the given list, some of the tender annuals may occasionally be considered as less tender; as Amarunthus coxcomb, and tricolor, balfams, double, as well as single, and stramonium; only they will not be so forward and fine. Some of those also among the less tender may be sown

hwn as hardy, for a late blow, as China-after, Indian jink, love lies bleeding, French and African marigold, princes feather, ten week flocks, and fweet fultan. Some among the hardy annuals may advantageously be treated as the lefs tender, to ensure their germination, or to bring them forward, as behvidere, Indian corn; (the large fort of which must be forwarded upon heat) mignonette, malarry blight, nasturtium, and persicaria.

### The CULTURE of each Class follows.

### I. OF ANNUALS.

ABOUT Mid-March is a general good time to fow the TENDER (and in thort all) forts, though the curious and skilful being well furnished with proper frames, &c., may begin a month sooner; the end of March, or beginhing of April, is, however, not too late, and will (perhaps) better suit a young gardener than if he fowed earlier. In order to succeed in this business, there should be provided fine dry and rich earth, good stable dung, frames and lights, or roomy hand-glasses, and mats, to cover.

A moderately strong hot-bed, for a one light, may be prepared, and the violent heat being certainly over, the keds either sown thinly in drills, two or three inches atunder, on five or fix inches of mould, or less on a weak bed. May sow also in pots, plunged to the rims. Cover the seeds from a quarter to half an inch, or more, according to their size. Some of them will appear in a few days, and others will lie a fortnight, or more, according to the circumstances of their particular nature, age, and the heat, or moissure, they meet with in the bed.

Thin the plants a little in time, and foon after to an inch, and then again to two, afunder. By no means let them be crowded, which would draw them up weak,

and occasion a crooked growth; whereas a robust and

erect stature is the beauty of any plant.

Water, just warm, must be gently given them, (not to beat them down) as they may appear to need it, and air (particularly in a full fun) as much as they can be fun thought to bear, a little at first, and by degrees more, for this is effential to their health and strength.

The feeds may also be fown in pots, and plunged at a he the back part of a cucumber or melon bed. A bed may may be got ready to prick them into, or into pots placed in by the like manner; and where only a few are cultivated, of this method is advisable, (to fave trouble) not beginning adv

too early.

Provide another bed by one month from the fowing, to fet the plants out in; and having fix inches depth of mould, place them five or fix inches afunder, allotting those to the warmest part of the bed which were longest coming up, and which are of course the weakest, as globes, &c. or they may be put out in small pots of five inches diameter: Place the tallest behind. Let the mould be warmed through before planting. There had better be too little, than too much heat; but if the bed gets over cool, line it, or cover round with straw, as directed in the management of hot-beds, page 174.

If not fown till the beginning of April, this fecond bed may possibly go through the business, with proper management to keep up its heat, and covering well on nights; but a third bed is commonly necessary, in order to fucceed well, and bring the plants on forward and fine. In this bed, it being covered over with four or five inches of mould, the plants should be in small pots, one in each, and plunged an inch deep, close to one another. As the bed gets cooler, the pots are to be earthed higher, till up to the rims in mould; but if planted without pots, the distance should be eight or nine inches asunder.

More water and air is necessary as the plants increase in fize; and every time they are shifted, let it be carefully, with some earth about their roots; though

a warm

and warm bed will foon make them strike, if without nould. Let them be shaded from sun a few days; i. e. nould. Let them be shaded from sun a few days; i. e. (not ill rooted in their new habitation. As these tender and annuals do not rightly bear the sull open air till Midne summer, give them resolutely as much of it as possible ore, in the frames, (by degrees) even to taking off the glasses in the middle part of sine mild days. Keep up as a heat in the third bed as long as can be, that the plants may continue in a growing state, and not yet stunted by cold at bottom. To this end, a fourth bed, for some sted, of the sorts, as globes, coxcombs, &c. would be a great advantage as to size, especially if the weather is advantage as to fize, especially if the weather is unkind.

It is hardly necessary to hint that the beds must be h of larger, and frames deeper, every time the plants are ting hifted. As the first frame was a one light, let the gett second be a two light, and the third a three light, which as may be raifed upon bricks, or boarded round the botfive tom, as occasion may require. From the small pots, the let them be transplanted into bigger in time, or (as foon as they can fafely be) into warm borders, where, if covered with hand-glasses, set on bricks for a while, it would fecure them from unkind weather, till got a little hardened. In this changeable climate of England, there is hardly any knowing when tender plants may. be exposed fately; yet too much housing and covering. is to be avoided as much as possible. Many slowers will need support. See page 55. For the method of bifting plants from pots, as into bigger, or to the open ground, see page 184.

Some of the tender flowers in pots may be plunged to the rims in the ground, to keep their roots cool, and for the fake of being conveniently covered; in which case, it is proper to put a bit of tile below the pot to keep out

worms.

Good feed from tender annuals will not be well had, but from February fown plants. Skilful gardeners, lowing early, and having plenty of dung and drawing

frames, produce surprising plants of the tender annual class; so that the globe amaranthus has been raised to three, and the giant coxcomb, and tricolor, from three to five or six feet high. Flowers designed to gather seed from, should begin to have some protection of glass about Mid-August, at least on nights, till they are fully

ripened in September.

Scoop trowels, of two or three fizes, will be found very useful in the shifting of slowers in general, but particularly of the hot-bed sort; and as they should be clean from dirt when used, so also should they be free from rust, by which they will work much pleasanter, and more successfully: In short, all garden tools were better kept bright, as well for use as neatness. Before a trowel is used, in the removal of a plant, it is a safe way to cut strait down round the root, and to the bottom, with a large, clean, and not very blunt knise; so will the trowel take all up whole, and the sibres will not be lacerated, or barked: But attempt not to take up more earth in a ball than is likely to hang together, lest all drop by its weight. Transplant (if possible) always in moist, or cloudy weather.

A fmall watering pot, (i. e. from two to three quarts) with a finely pierced rose, is also necessary, to give refreshment without bending down the plants, or hardening the surface of the earth. The form of many a good flower is spoiled in its infancy by rough watering, and particularly capsicums; to avoid which evil, what-

ever pot is used, let it be only half full.

The potting of plants is often carelessly, but cught to be most carefully performed, that as little check as possible may be felt by the roots. Fill the pot one third, half, or more, full, (as the case may require) and then make a hole in the middle, adapted in form to receive the plant, with its ball of earth; and do it right at first, so as not to be too high, or too low, for once put in, it will not be safe to take it out again, less the mould drop from the roots. Do not press the ball of earth,

earth, (as some do) but only just fasten the loose inual mould that is put round it. If the foil is light, press d to that a little which is first put in at the bottom. If a ee to plant that is to be potted be without mould about its Jeed roots, raise a hillock (at a proper height) in the middle glass of the pot, to lay the roots on and round: It must fully always be avoided planting in the pots too deep, because to much of the pot is lost as is above, except the fort is ound apt to strike root above, as balfams. In all transplantations, it is proper to shorten some of the roots, and the d be most straggling are to be chosen for the purpose; so that free

large. Annuals in pots will require water every day, in very hot weather, and in moderately 10, every other; but those in the open ground will do twice as long (or more) without water being given them. Some forts will need more water than others, as egg plants and balfams, than coxcombs and tricolors. This matter, and a variety of others, will be learned by observation, without a talent for which, no one can possibly become a good gardener. The most exact directions will not take in every case, and rules will be of little avail,

when it is done with a ball of earth, some of the external

fibres must be cut off, if it was not done by taking up,

which it generally is when the plants are any thing

where the mind is not in diligent exercise.

In general, potted plants require water according to the weather, their fituation as to the fun, the fize of the pots, the fulness of the roots, the quantity of leaves, and the particular nature of their substance, as succulent or not: The smaller pots must have it the more frequently. The earth also in which plants grow makes a great difference, as some forts of soil retain moisture much longer than others. It may be a question whether pots of annual flowers standing in pans, thould have water constantly kept in them, or only watered (in due time) on the top, till it runs through: Both practices are followed by good gardeners; but the latter I think

th

think best; as keeping the young fibres at the bottom always fodden can hardly be right: With respect to perennials, (except of an aquatic nature) it must be wrong. Let pots of flowers in the summer be placed pretty much in the shade and shelter; but not by any means be under trees, or a roof. A fituation where they have only the morning fun till eleven or twelve o'clock is the best; and some persons are so curious in this respect as to have awnings for the purpose, and temporary reed fences to keep off the wind, to which flowers (particularly of the tender kind) should not be wholly exposed. Annuals, or even a few perennials, may be put in covered places, when nearly in full blow, for the fake of their ornament; but the latter should not be continued longer than while the prime show lasts, for it will make them weak and crooked.

It is advisable not to pot more hardy plants than necessary, as they occasion much trouble, if properly managed; and after all, will not be so fine as those growing in the open ground. Some things are too tender for open culture, and by potting they are conveniently protected by frames, or by housing, and sometimes simply plunging them in the ground, close against a warm wall, in winter, where a little protection may be easily given them. Others it may be desirable to pot, for the sake of moving them into particular places, when in blow, and to have some ready to put into the ground, where others are gone off, so as to keep certain savourite borders and walks always well surnished; but do not have too much to do in this way.

A fecond fowing of tender annuals should take place three or four weeks after the first, according as that was made, late or early; for their beauties are certainly desirable, as long as the feason will permit us to behold them, and they are the florist's chief dependence in the autumn, when, if he is emulous to do well, he may make a noble creditable show. See list 7, in next section, with the observations.

The LESS-TENDER annuals should have a slight hed (about two feet thick) made for them at Mid-March, or a little after, being fown and managed as directed for the tender forts. When they are one or two inches high, (according to their nature) they must be taken up with a scoop trowel, so as to keep a ball of earth about their roots, and either transplanted on another bed, about one and a half foot thick of dung, or into the cold ground; the small kinds at four or five, and the larger at fix or eight inches afunder, in a good well broke foil. Let them be immediately watered and kept moift, and shaded from sun till well settled. Here they may grow till their leaves begin to meet, when they hould be cut between their roots with a knife, and lifted up neatly with a scoop trowel, to be potted or planted where they are to flower: If this business is done well, they will receive but little check in their transplantation. Spindle rooted plants (as flocks) should be moved where they are to blow, as young as may be; but fibrous

Plants will flag a little even when removed with a large ball of earth; because fome of the fibres of the roots are either broke or cut, and a plant is chiefly fed by the youngest and most extreme parts of the root. If possible, let all fummer transplanted flowers be shaded from sun, by garden pots, (raised a little) or otherwise, till they have struck fresh roots, which they will soon do; but uncover on nights. This will occasion some trouble; yet the advantage attending it makes it very advisable, if not absolutely necessary, and especially when the plants are moved with none, or very little

rooted ones may be thifted much older.

mould about their roots.

A hot-bed for these, as it is moderate, may be covered with hoops and mats, and do very well, or rather better than frames and glass; for it often happens, that annuals

are kept too close, by which they become weak, and get stunted when planted out in the free air, made, by over-nursing as it were, unnatural to them. To wards the end of April, almost any of them will come up under hand-glasses, or even without, on a warm border, in a light and rich soil; but they will blow late, and be not near so strong. The Chinese hollyhook, though it will certainly come up well at this late sowing, will be hardly able to make a show before winter. Those slowers of this class, however, that have been mentioned to be occasionally considered as hardy, may be thus treated for a second blow.

Other modes of cultivation are, that a few of the less tender forts may be sown in pots, and placed (not plunged) in any hot bed that is in work for other things; but they must not be kept close, or hot, which would draw them up weak: This plan may do so them a little while, and a slight heat may be got ready to prick them out upon, when air may be given them

freely.

Again, both this class of annuals, and the former, if not very early fown, do exceeding well, (or rather belt) when on hot beds, under hand glasses, or paper lights,

particularly balfams.

What was faid of tender annuals apply here, as to air, water, and cover, but more freedom in the present case is to be taken. If any are under mats, the cover must be removed on days, except the weather be bad; or it may be only turned back, and half off, to let the sun and light in from the south. Never let either the seeds or plants of annuals really want water when the weather is dry. See page 55. See List 8 in the next Section, with the observations.

The HARDY annuals have fome little difference in their temperature. Though all may be fown from the middle

middle to the end of March, as the best average season, and middle to the end of March, as the best average season, by some may generally, with safety, be sown at Mid-FeTo-bruary, as candy tusts, cornbottles, larkspurs, bawkweed, some savatera, label's catchfly, supines, dwarf sychnis, nigella, same sweet peas, poppies, mulberry blight, oriental mallow, late, persicaria, sun-flower, annual snap dragon, Venus's looklook, ing-glass, and navel wort, virginian, or annual stock, sowand winged peas, with some others.

But nature seems evidently to direct an autumn sow-

But nature seems evidently to direct an autumn fowing, for many forts which are then shed (some always, may and others often) come up at spring, and these make he finest blow, and produce the best seed for propagaion. A number, (all the above forts) therefore, might be scattered on the surface of the ground at random, not immediately as soon as ripe, but kept a little while to harden: This however is not a common practice, as gardeners like to have their borders at liberty to spring tress before they sow their annuals.

For the spring sowing, (about Mid-March) the tround being deep dug, and well broke, make hollows

round being deep dug, and well broke, make hollows by drawing the mould aside) of from six to twelve inches diameter, or more, according to the size of the parden, as large ones should have the biggest patches. low thin, and cover according to the fize of the feed, from a quarter to an inch deep. Take out mould mough to leave the patches somewhat hollow, which will ferve to show where they are fown, and to receive the rain, or occasional watering. It may be proper also put a bit of stick in the center of each, as a mark, that the feed may not be disturbed. If the plants come up rowding, be fure to thin them foon, and leave only a number suitable to their usual fize of growth; as one the belvidere, cornbottle, persicaria, and sun-flower; wo of the lavatera, oriental mallow, mulberry blight, ic. three larkspurs; and four of less plants. Annuals te very often fown too thick, and fuffered to stand too lose for flowering, and that altogether not by nelest, but choice; yet a few thort strong plants with

fine full flowers, are furely better than tall danglin

A fecond, or even a third, fowing of hardy annual may be made, at two or three weeks between, to con tinue the blow, especially of those that come early and are foon off: Mid-May is not too late. The lark four, for instance, will make a long show with us, b autumn, and early and late spring plants; in short of every flower that blows in fummer, there may be thre fowings, and two of those that come early in autumn

in order to a full fuccession.

Hardy annuals do not in general transplant well, f should be sown where they are to remain, and the must have a good soil in order to success. Take care to fow the tallest forts behind, and the lowest in front, an to form the patches at a fufficient distance from on another, that the ground may be stirred and raked between them. A garden may be too full of flowers, which i certainly is, if the earth is not feen about them; for when that is clean and fresh, all things growing in i appear more lively: It is, as it were, the back ground of a picture. A few hardy annuals may be fown in pots, fetting them where they have only the morning pots, fetting them where they have only the morning fun, and when in flower, they will ferve to put into on any particular place for ornament, or be turned ou into the open ground, where fomething may be want-

## 2. OF BIENNIALS.

There are but a few of these, and the principal fort will be found in the lift of them, next fection, where observations will be made on particular plants.

These are to be sown in drills, or in beds, at broad cast, the latter end of March, or beginning of April where they have only the morning fun, and the ground Choule

ould be cool, or kept fo by occasional watering: he beginning of May, however, is not too late.

Thin the young plants on the feed beds a little, foon ter they appear, to about an inch, and again to three four inches afunder, and keep them well weeded. hey may either thus remain till autumn, to be planted it where they are to blow; or if they grow too strong d crowding, let every other be drawn in fummer, husing a moist time, if possible) and planted out wing fpring: The latter feafon will do for final anting, though the former is best, as the roots get they hablished in the ground; when if moved in the spring tre to bey meet with a check. It is best, if possible, to an ampliant with earth about the roots; but thorten all nggling fibres, and cut off dead and rambling leaves.

Infevere winters, those moved in autumn (if not very very) are sometimes killed, and therefore a few may be for derved to fpring, in case of such an accident; when in it eing moved with good balls of earth, they will not be such checked. It planted late (as November) let them ave fine well broke earth about the roots, and lay sols, old bark, or small stones round them for protection from frost. Some of the Perennials might form nother class, and be called Biennial-Perennial, &c. om their uncertain continuance.

# 3. OF PERENNIALS.

This class (as has been observed) is very numerous, and the plants are propagated, many of them by their wis, according to their nature, as fibrous, bulbous, &c. ome by layers, suckers, offsets, flips, cuttings, and a w by feed only. All forts (bearing feed) are occaonally propagated this way, for new varieties, or to roduce finer plants, as those from feed generally prove, ith respect to strength, symmetry, and flowers. It

happens, however, when propagated from feed, the though sometimes a better, more frequently a less beaut ful flower is produced of many forts; and this is the re fon why the other modes of propagation are fo muc adopted, by offsets, &c. as thus they come identical the same with the mother plant. Another obstact against some forts being sown is, that they are seven years before they come to bear, as all bulbous, and to berous rooted flowers.

The Dutch have made themselves famous by the patience and perseverance in raising bulbs and tuber and fow every year some of each kind, which pays the well, when they meet with an eminently good flower A new fort of anemone, auricula, carnation, ranunculu and even a polyanthus, will frequently fetch a guine

and a tulip, or a hyacinth, sometimes ten.

To raife bulbous and tuberous rooted flowers, the should be fown in boxes (suppose three feet long, tw wide, and fix inches deep) of light rich earth, abou the middle of August, or September, and fetting them i a funny sheltered place not under cover. Sow anemone and ranunculuses a quarter of an inch deep; irises, the ebicums, and cyclamens, half an inch; and tulips, frit tillaries, and hyacinths, near an inch deep, giving wate in a dry time, so as to keep the mould somewhat moint but not wet. A little hay may be kept over the feed till the plants appear, which perhaps will be spring with some. Sowings may take place also in March or April, removing the boxes in May, to where they may have only the morning fun. Thin them a little if they come up thick, and when the stalks die, put or half an inch of fine mould; and after the decay of the leaf next summer, they must be planted out in nursery beds, (latter end of August) two, or three inches asunder, (according to their nature) and some will blow the following year, as the anemone and ranunculus, &c. though the hyacinth will be four, or five, and the tulip seven or eight first. These must be removed from the

e first nursery bed to another, (as soon as their tops e decayed) and planted at fix inches diffance; and eaut e decayed) and planted at his second record and planted at his second record record as blowing plants. Keep them very rar of weeds, particularly the feedlings; which protect much favere weather from frost, or heavy rain, by mats icall d hoops. A reed hurdle, or fomething elfe, put up the N. E. end, to break off the wind when it is harsh, ill be proper.

It is not absolutely necessary to take bulbs and tube up every year, as every fecond or third may do; b it is the common practice, because it gives an opposit tunity to remove the offsets for propagation, and the mother bulbs are thus strengthened, as also from the renewed foil they meet with by a fresh plantation. is not uncommon for bulbous roots to be fuffered stand many years without taking up; but then the cramp and starve one another, and are apt to go of from their original beauty.

Bulbs and tubers may be either replanted immediate on being taken up, or kept out of ground during the natural periods of rest; or for some forts even longe as Anemony and Ranunculus, for several months. A tumn flowing bulbs are to be taken up in May, if the

leaves are decayed.

Spring flowering bulbs should be replanted in Sa tember or October; those of the fummer in October, November; and those of autumn in July or August. little before, or after, is not very material; only who they are put in too foon, the Spring ones come fo fo ward as to be liable to be damaged in severe winter and iprings; and when kept out of the ground too lon the bulbs spend themselves first in making roots. The fealy bulbs (as lilies) should not be kept out of the ground above a month or fix weeks. Those th flower in fummer, may be put in the ground at differe post times, as early and late in autumn, and early in the new year, (not later than February) to obtain a su new year, (not later than February) to obtain a fu cession of blow. If any are put in at the end of Februa according of March, they should remain two years the for increase. This is a common practice with the months. anemone and ranunculus; but when planted in winter include the foil should be a dry one, or made so, by digging in soot good quantity of fine sea-coal ashes, and coarse, or drie at stand; else they are apt to rot, if much wet falls, best they have started sibres, especially when followed this that but tuber tharp frost. They may be protected from wet by mats, and from frost by peas haulm, or wheat straw.

Offsets of bulbs, and weak tubers much have

Offsets of bulbs, and weak tubers, must be planted amonth before the full-fized roots; and as they are not expected to flower the first year, should be disposed of in nursery beds, (rather close) where they may grow red to a year, or two, according to their strength, as some the will be this time, or longer, before they flower. Those taken from scaly bulbs, will not endure to be out of ground, and must therefore be planted almost immediate

the will be this time, or longer, before they flower. Those taken from scaly bulbs, will not endure to be out of ground, and must therefore be planted almost immediated ately. Bulbs taken up out of scasson, i. e. when they have remained so long in the ground as to have struck out fresh roots, should be removed with balls of earth, the strength of the be exceeding weak; it is therefore necessary exactly to observe the proper scasson for removal.

The soil that best suits bulbous and tuberous roots in general, is a sandy loam; but most of the sorts are not well dug, even two spades deep, that their fibres may so so to see, and wet be completely drained from them, when much of it falls. This work should be done a week before planting, that the ground may settle. In the light soil, roots of the ranunculus have been found to so the strike a yard deep, which may admonish, that in a clay be the bottom, it is proper to lay a body of stones there, (suppose at eighteen inches) that too much moisture may in the struck of their size, three or four inches deep, from year their top. Tubers also according to their size; anethe struck of the ground, as crown imperials, and crocuses, or did the surface of the ground without damaging them, shall tix inches, or more; some persons, therefore, plant them deeper than the above rule, in order to be able to got the surface of the ground without damaging them, shall tix inches, or more; some persons, therefore, plant them deeper than the above rule, in order to be able to got the surface of the ground without damaging them, shall tix inches, or more; some persons, therefore, plant them deeper than the above rule, in order to be able to got the surface of the ground without damaging them, shall tix in the advisable.

sha but it is not advisable.

The proper disposition of bulbous and tuberous room is either in beds (a trifle rounded) of from three to fou feet and a half wide, for the curious forts; or in patches to form clufters of three, four, or five, agreeable to th room they require. There should be only one in a place (generally) of the white, or orange lily, crown impe

rial, and fuch like large bulbs.

In beds, the fancy forts of bulbs, and tubers, may b fet in rows, eight or nine inches afunder, and from five to feven inches in the rows, according to their fize. The distance of four inches apart is, however by some florists, thought sufficient for anemones an ranunculuses; but certainly more were better, where strong blow is a first object. Hyacinths should be planted at feven, or eight, though they are more com monly fet at fix inches. Tulips should be at eight, o nine, though fix is often all that is allowed them.

When planted, if rain does not come in about for days, beds of bulbs and tubers should be watered, t

let them growing, that they may not rot.

Though bulbs may be planted by a dibble, (taking planted to be a dibble, (taking planted to be

Those bulbs and tubers in beds, may conveniently libe protected, when in flower, from rain and fun, by a fine perfection of an awning, which will continue them in perfection blov

to the flowers, in beds, first break ground, if the weather stebre is severe, they may then have an awn.ng of mats, or to the doth, occasionally over them; or a little peas haulm, place or wheat fraw, laid thinly on, just to protect them in imperient tender state a little; this regards particularly rights, for on days a cover should not remain on in to-easy be leaded weather. But before the shoots appear above from ground, valuable beds of these slowers should be sheltered from having much wet, (even all through winter) rever as moisture gives frost so great power. It a body of so move lies on, it should not be suffered to melt there when it thaws.

Spring flowering bulbs may be brought forward by come when it warm rooms, or hot-beds; and thus, even in winter, we may have ornaments and sweets that court is so an admiration. The great variety of byacinths and did, to whanthus narcissus, surnish us amply in this way; but where early bulbs may also be thus forwarded. Pots, aking baced in a warm kitchen window, may be brought forted any window, open to the south, it will forward them.

These should be potted in October, and have a light dry sew bill, occasionally giving water. Bulbs may be put in memory light or a succession. Let the bulb just touch the water, which should be soft, and replemined so often as to keep the step of a pea, be put in each time, it will strengthen each be blow.

Though bulbous flowers are propagated plentifully the orter of the step, yet some are increased from little bulbs are of the step of the step, yet some are increased from little bulbs are of the step of the step, yet some are increased from little bulbs are of the step of the s

Though bulbous flowers are propagated plentifully of root offsets, yet some are increased from little bulbs ormed on the sides or tops of the stalks, as the moly sibe, and the bulbisorous lily. These should be taken for a nursery beds as offsets.

But spring cuttings, treated as the arbutus, is th furest method to make difficult forts strike root.

It may prove an observation of some use, that tree and shrubs raised from feed grow the largest, from layers generally less, and from cuttings the leaf less Where budding can be practifed, it is preferable t graffing for the propagation of shrubs.

For planting and managing shrubs, &c. see section of

For pruning, see page 166.

# SECTION XIX.

#### LISTS OF TREES, SHRUBS AND FLOWERS.

\*\*\* The names of the choicest forts of fruit tree will be found in fection 17.

THE modes of cultivation are here directed by t letters, as in last section; adding m. for moi w. for wet, and d. for dry. Those not marked are be understood as (pretty much so) indifferent as to so and indeed those marked otherwise may grow in a co trary kind, and often do, though not fo flourishing or fafely as to extremes of heat or cold.

The time of flowering is annexed to those trees a shrubs that are thus at all ornamental, and the mo ordinary heights they are found to attain are denot in the arrangement; a circumstance hitherto mu wanted, as uleful and necessary to be known, in or to a right disposal of them. Those of a naturally is growth have been, sometimes, planted behind in shr

XIX

e t

on d

tree

y th

CO

ng

s a

mo

not

mu ord

y 10 bra

th bries, &c. and the taller forward; but yet this unformate circumstance must be unavoidable to every inextree prienced planter, who has no other guide, than that from his is a tree, and that is a shrub, which are vague, inleast definite terms as to stature.

The colours of the flowers are generally mentioned, s agreeable to be known, and of use in the disposal of trees and shrubs at planting, to diversify the scene with more propriety. In a few instances the flowers, either s to time or colour are not noticed as being too infigniheant to be ornamental, though the fruit, or foliage,

or both are.

Such observations, as may be thought most useful and necessary, will follow each lift; but as neither all the forts, nor the varieties of each fort, could be enumerated in fuch a work as this, so also the minutiæ of propagation, &c. is more than could be comprehended, or expected: Fólio volumes (so copious is the subject) have left a variety of plants unnoticed, and much unaid respecting cultivation. For ordinary use, a greater numeration, or more enlarged particulars, would indeed have made the book less valuable. If the selection and information is good, (and pains have been taken in the business) those for whom this book is designed, will have no reason to complain.

The names of trees, shrubs and flowers, are in many ases various, as sometimes a scientific name prevails, and at other times a trivial; and of neither is there a perfect agreement, for of both there is often more than The object therefore here has been, to give that mane by which each is supposed best known. Different plants are fometimes called by the fame name, and a nice discrimination is made by botanists, according to flower, leaf, &c.; but these are no farther noticed than necessary. Such descriptions are given of each, as cannot (it is h ped) fail to identify the fort, when applied

for to any nurseryman.

For underwood amongst forest trees, the usual sorts are, alders, ash, beech, birch, hazel, hornbeam, sallow, willow, and sometimes the wych-elm, common maple, poplar, and sycamore.

#### OBSERVATIONS ON PARTICULAR TREES.

Alders, cuttings of it grow readily, and may be thick truncheons a yard long, pointed, and thrust into soft ground half way, or into a hole made with an iron bar. This is the way also to propagate poplars, willows, and sellows; also elders. There is a dwarf alder.

Ash, the American forts do not grow near so large as the common English. For the ornamental ashes, see

the next lift.

Birch is reckoned the worst of timber, yet the wood has its uses in several particular businesses. The American sorts grow much larger than the English. The tree is of that accommodating nature, that it will grow in any soil or situation, wet or dry. It is well known, that a wine is made of its sap, by boring holes in sull grown trees in spring, before the leaves come out: from a number of trees a great deal may be collected. Without being unpleasant, (if properly made) hirch wine is relished by many, and is reckoned very medicinal in scorbutic, and other complaints. There is

It has been the wish of the author to speak of the medical properties of many plants that have occurred in this work, but room could not be allowed it. The process, &c. of birch wine, with the properties of most plants will be found in Meyrick's Family Herbal, 8vo. a good book.

EC

rna

A

A

B

a method of catching the liquor, by putting into the holes (deeply tored) faucets of elder. See next lift.

Chefinut, ornamental. See the next lift.

\* Elm, the wych is the quickest grower, and with your flourish in any soil; but the broad leaved is reckone the best timber, and the small leaved the most orna elder mental: it should have a good soil. The wych is easily han raised from seed, (sown directly after it is ripe) but the swother forts are propagated from suckers, or layers, or layers, and shoots for layers, stools are to be formed by cutting down sour some young trees, almost close to the ground. Trees from hole layers are better than from suckers. Observe, the subatever is to be propagated by layers, or suckers making stools is the way to procure them.

Hornbeam, the common fort will grow very large in lact fome foils, but the Virginian (flowering yellow) will be hardly reach thirty feet, and the bop not above twenty sthe The bornbeam feathers down lower and thicker that any other tree, and the property of holding its decayed have on all winter, adapts the common fort for a lide force of from winds.

creen from winds. See page 111.

Nut tree, as timber, will be best propagated from he nuts, either to remain where sown, or planted out op while young, keeping the stems trimmed up, free of men shoots, to about five or fix feet, (according to strength) hee and then to form a head, topping the leading shoot for the purpose, which will occasion several branches to proceed from the upper eyes; and this is the way to form all forts of trees to good heads.

Oak, the English produces the best wood, but the American forts are the fastest growers, though they do not attain to the fize of the English. A cool strong soil produces the handsomest trees, and toughest timber. Oaks should not be above three or four years old before they are planted, for the older they are, the more check they receive, and it is a tree that does not transplant well. Hence all the care should be taken that can be

to the the business. See section 10. But oaks succeed best without removal, having a tap, or downright root, which is frequently broke in taking up: All trees would probably thus come finer, if it was convenient. The consequence of preserving the tap has been suffered; but it is certainly Nature's direction, for rather easily han give up the point, the tap of the oak will make it is way downward, in a direct line, through the hardest rs, ooils. See page 80.

Poplar to propagate by cuttings, see alder; but sounger and smaller cuttings for this tree do better, as from hose of one or two years old, and half a yard long: the black poplar does not succeed well by truncheons. Walnut, when planted for timber, should be young, and the tap root, if possible, preserved whole. The ge in lack Virginian grows more erect, but the other makes will be largest tree, and best wood. The white Virginian entry is the hickery nut. All these make the best trees, when that rown from seed without transplanting.

Willow and sallow, to propagate by cuttings, see or a lider.

#### OBSERVATIONS ON PARTICULAR TREES.

Buckthorn, if raised from seed, sow early in autumn, as soon as the berries can be procured, and perhaps some may come up the following spring, but most of them will lay another year. This is the case with other seeds, as sweet briar, &c. See page 78.

Catalpa should grow singly, that it may have its natural wide spread, and, if possible, let it be on a plat of grafs, where it will appear to great advantage. It is very hardy; but as it comes out late, it is advisable

to give it a favourable aspect.

Maple, of the scarlets, there are the Virginian and fir Charles Wager's, both very ornamental, but the latter most so. The Mountain hath shining leaves, and continues late in autumn.

Magnolias are to be confidered as rather tender, especially young plants. The glaucous leaved is of the lowest growth, (about ten feet) but all are elegantly ornamental with their white slowers: There is also a blue slowered one. Let them have a dry foil, as all tender plants should, as well as a warm situation.

Mountain aft produces its white flowers in May, but they are little ornamental. Its foliage, however, is pretty, and its fruit of red berries is one of the greatest ornaments of autumn, coming very early, and hanging all winter, if the blackbird, &c. will let them alone. As it deserves the most conspicuous situation, it will be proper to plant some near the house, and where birds may be disturbed from too frequent visits.

Pishamin, or date plum, is chiefly cultivated here as ornamental for its shining leaves; its fruit is, however, eat by some, like the medlar and serb, in a state of decay. House young plants in pots the first winter: Al-

low this tree a dry foil and shelter.

Pistachia, this is the hardiest of three sorts. Treat it as a tender plant, whilst young, for three or four years,

years, and let it have finally a sheltered situation from

wind, and a dry foil.

Tulip-tree is tender whilst young, but afterwards very hardy; is uncertain in slowering, but handsome in its leaf and growth, and has been used to be planted singly on lawns, &c. It is a native of Virginia, where it attains to so vast a fize, as to be from twenty to thirty feet in girth, though here it keeps pace only with an ordinary elm.

Virburnham, or way-faring tree, is very pretty, in its hoary leaves, and white flowers, succeeded by fruit in autumn, in bunches of red berries. The American forts grow not near so high, but they rarely ripen their berries here. The variegated fort does not grow so large as the plain, which is the case with all striped

plants. See next lift.

# OBSERVATIONS ON PARTICULAR TREES, &c.

Andromeda tree is tender, and must therefore have a situation accordingly. It is always a part of the green-house surroute, but does sometimes abroad; and it is very well to try what may be done with the bardiest

green-house plants.

Apple, these crabs produce rather slender wood, and therefore should not be in a crowded, or shady situation, but rather, as much as possible, in detached single plants. The fruit of the three first makes superior taris, and the latter an excellent preserve; and the fruit of all of them may be introduced in the defert, when full ripe. Allow the double slowering apple a good situation, to preserve its charming crimson blow as long as possible.

Azederach confider as tender; its foliage is beautiful,

flowers white, and fruit yellow.

Cashiobury bush must have a sheltered situation, particularly the young plants, which should be protected for two or three winters.

Spindle tree (sometimes called prickwood) is very beautiful with its leaves in autumn, for which (as many other plants) it is chiefly considered as ornamental, its flowers making no show. The seed lies two years before it comes up.

Layers require two years to strike. Cuttings manage as directed for arbutus. Seeds are imported from Vir-

ginta.

Trumpet flower, sometimes called scarlet jasmine, is a trailing plant, and therefore requires training to a wall for support; or having something to climb on it will proceed much in the way of an honeysuckle. It is rather tender, and must have a good situation, but when properly managed is a great beauty. Prune it to a few eyes, precisely upon the principle of a vine. The shoots will strike into cracks of the walls and mount high where there is room. See Catalpa, last list.

#### OBSERVATIONS ON PARTICULAR SHRUBS.

All-spice-tree must have a warm and dry part of the shrubbery. The whole plant is aromatic.

Aralia, thorny, is propagated by pieces of its large roots, and perhaps many plants might be fo: In this

way, the pyramidal campanula fucceeds.

Azalea likes cool ground, and rather shady; must be sheltered as to winds, and in this climate should rather have a dry soil, kept cool by occasional watering during summer. It is a very beautiful upright shrub.

procuring a wax from the berries of this plant to make candles of. It is rather tender, yet likes (as many American plants do) a moist foil; let it be well sheltered from bleak winds.

Clethra is an elegant shrub, slowering all summer

and even winter; it prefers a moist soil.

Coluted is too tender to abide severe winters, but in general will do, with a little attention: Its slowers are pretty, of a bright yellow. The other sorts (three) are more tender, and are to be potted for protection

from frosts, by housing them.

Cytifus, deciduous and evergreen, there is a variety of, and all very ornamental, with their yellow flowers. They are rather too tender for the open ground, and the hardier forts here mentioned, if tried abroad, must have a dry warm fituation. Seedlings should be housed, or well protected in frames for the first winter, but not kept too close.

Germander tree treat as tender, for though it will live

abroad, it is mostly a green-house plant.

Hydrangea confider as rather tender, and pot some: it can hardly be kept too moist at the roots.

Mallow tree manage as the cytifus, though it is not the a

quite so tender. All feedlings that can be brought up in the open air, make much finer plants. The tender forts thould be put out in nursery-beds, and occasionally protected by covering, and some potted to be occasionally boused.

Poison trees, even the touch of the leaves of these plants will affect the skin, but the sap is very (even

angerously) acrimonious.

SECT. XIX.

Pomegranate must have a good fouth wall, and rich the foil. The double fort should be occasionally matted in sher sher frost. In very favourable situations (however) they have succeeded in espaliers, dwarf, half, and even full standards. The best season for planting the pomeganate is in spring, when just beginning to shoot. It ake is rather rude of growth, and must therefore have timely training. The principal pruning should always the in autumn, and from time to time all straggling, aperfluous growths taken out, that shoots may be enouraged to put out strong blossoms, in the fullness of which the great merit consists. These bearers should the fix inches, or rather more, afunder. The mode of lowering is at the ends of the young shoots: nothing quals this plant in finences of blow. The double fort s more commonly planted; but the fingle flower is very beautiful, and its fruit, which will ripen in fnug avourable situations and seasons, makes a fine show lo, especially when burst. Both flowers and fruit are

res, and favery fine fearlet.

Rose claims precedence of other shrubs. In its vamited the street of the street o

The order of blowing may be reckoned thus: Cin-unon, (sometimes called the May-rose) monthly, damask, ne: urnet, Scotch, Pensylvanian, apple, &c. Then the stell roses we have, are those of the mont bly again, and not the musk. Occasionally every fort may bear a few late nite ones, but chiefly the Provence. To encourage this **fhrub**

thrub to treat us in the latter part of the year, pulling off the first roles, as foon as they begin to decay, is means; but to pull off all the buds, at the usual time of blow, from a few trees, is a more certain method A more fure way still, is to top the new shoots towards the end of May, or prune down to two or three eyes These manœuvres should be particularly exercised or the monthly forts. Transplanting roses in spring, is means to effect a middle blow; and if into a North border, and cool ground, this may be done late in April, or even in May, (occasionally watering) pruning at the same time thort. Early roses are obtained by being trained against a fouth wall. The monthly thu planted, and having glass (as the light of a cucumbe frame) put before it, will fometimes come as early a the end of April, or beginning of May. It is a good way to put mofs round the roots of these wall trees in March, to keep the ground warm, and at the same time moift, which helps us to both forward and large rofes In dry fituations water.

To dispose rose trees to bear forward, the not suffering any slowers to blow the present year, and pruning short in July, or August, is a means from which much may be expected, especially if there is any artificial warmth used in the spring to force them. With view to this, some good brushy rooted, low growing plants, may be potted in autumn, not suffered to beat the next summer, and being pruned down (as above will force well the next spring. Rose trees potted so an ordinary blow, must not be in too small pots, no placed in a warm situation, except early in spring, and

must be kept cool by frequent watering.

As to the propagation of rose trees, many will sen forth suckers enow, and those that do not, should be layered, by slitting (as carnations) or budded; but make two years before they root. See page 66. Som will come by cuttings, but uncertainly, as the burgund &c. The China evergreen, or everblowing rose, take

well by cuttings; but it will not do abroad, except in the summer months, and therefore is not in this list: There are two colours pale and deep red: It grows low, and rather weak. The burnet, apple, or any other sort, producing good seed, may be propagated that way; but it is a slow way, the seed seldom coming up till the second year. The double yellow rose blows indifferently, but when sair, the slowers are very beautiful. Plant it against an east wall, and in dry, but strong ground.

Snow-drop tree is confiderably ornamental. Layers will be two years in rooting. If raised from seed, (imported) fow it as soon as it arrives, in pots, or loxes, and house before frosts come. If they come not up the first year, set them on a gentle heat the sollowing spring, and they will soon appear. Shelter the

feedlings in a frame, or a green-house.

Tutjan grows wild in woods, and will therefore do well in the shade, as among trees. Every shrub, or plant, that will slourish in such a situation is valuable; and a gardener's attention will be well employed to discover them, by trials, &c. The St. John's wort, and St. Peter's wort, (allied to tutsan) may be planted in the shade.

Willow herb, as its roots run much, should some of it be potted; and as it loves moisture, may be set in

the shade, and kept well watered.

#### OBSERVATIONS ON PARTICULAR TREES.

Andromeda tree should have a dry soil, and sheltered

stuation; protect first winter after planting.

Arbor vita, though both forts are in estimation, yet the Chinese is most ornamental. Naturally they are of large growth, and hardy, yet formetimes the Chinese fort is kept in pots, as an agreeable companion (for

everal years) of other exotic evergreens.

Arbutus may be propagated from the first young hoots of the summer, planting them in pots, and puting them in a moderate hot-bed, (rather of bark) covering close with a hand-glass that is air tight; and thus most tender shoots of woody plants, which are found difficult to strike, may (most probably) be made to grow, as the bay, celastrus, cypress, &c. tried on a warm border, keeping the earth cool, and the glasses close. If the cuttings are planted just within the glass, watering well round the outside will reach them, and thus they need not be uncovered: If the glasses are taken off for watering, it is not (however) material, if they are carefully fixed close again. As from as the cuttings appear clearly to grow, air must be given them. See next lift.

Bay, the common plain fort is rather tender, and requires a fituation sheltered from bleak winds; but the variegated and double flowered forts are tenderer fill; and as they rarely succeed well abroad, they are

commonly confidered as green-house plants.

Cedar, the Bermudian, is tender whilst young, and

hould have a favourable fituation afterwards.

Fir, there is a variety of each species, denominated from the number of the leaves, and the shape and cod ac lour of the cones. The bahn of gilead, and hemlock, larg forts, are the lowest growers. To get the feed from the cones, lay them before a good fire, so as not to forch them; and if they come not out well, after

H

J

K

L

M

P

Pe

Pu

Ra

Rh

heating this way, bore a hole up the middle, and driv

fomething of iron in to split them open.

Oak, the evergreen forts are excellent timber, an very ornamental in pleasure grounds: See page 27 The red excrescences upon the kermes oak, are occasioned by insects making insertions in the bark for de positing their eggs, which causing an extravalation of tap, it there condenses, and forms the little granulous substances, used for scarlet dying.

Pine, there are several other forts of less estimation. The Weymouth and torch pines are the lostiest, and the Carolina swamp the lowest growers. To get out the seed, observe what is said above, as the pine cones are

harder to open than the firs.

Pyracantha requires some support of stakes, pales or wall, though it may be trained as a standard bust or form an hedge impregnable. It is very pretty whe in full fruit; but it so often misses being so, throug bad pruning, that it is got much out of repute: So page 169. It does best in a dry poor soil, and a eastern aspect. Young cuttings, in fune, will strike being potted in good earth, and set in the shade ti autumn, and then plunged in the ground under a warr wall. See observations on the Arbutus above.

- planted, they may fucceed abroad, and are worth the trial, as their place may, at any time, be easily supplied by some shrub from the nursery. While young, for winter or two, in severe weather, a few bushes laid tround, and a little peas haulm on the top, would say many a curious exotic, when they are nearly hardy enoug to endure our climate.

#### OBSERVATIONS ON PARTICULAR SHRUBS.

Adam's needle (yucca) is somewhat tender, and should be out of the way of cutting winds.

Andromeda tree is too tender for the open ground in general, but has survived abroad, our ordinary winters being in a favourable situation. It naturally likes moift soil; but keep the roots dry in winter.

Ciftus, all the forts are rather tender, but if brough up as hardy from the fowing as may be, and plante in a dry foil, shelter and sun, will stand ordinary wir ters abroad in the shrubbery, and prove delightful or naments: Cuttings do not make so fine plants as seed lings, but are hardier.

Cytisus, Spanish, must have a dry warm situation.

Germander tree, though generally confidered as green-house plant, it is afferted, by some, will endu ordinary winters abroad, with proper managemen Risk of experiment in these cases, or the trouble a tending, should not be minded, for if a shrub will live abroad, it is surely much better there; and it has been found

ces

ough

al o

1.

as

ndu

.

found that several things will do so, which have been

used to be housed, even in stoves.

Groundsel tree, or ploughman's spikenard, must have a foug fituation abroad, as hard frosts are apt to cut it; and if it is potted and housed, it must have a great deal of air, as it only needs protection in fevere weather. This is an argument for trying all things abroad, of which there is a chance of doing well, for they cannot have the air they require in a green-house, where are 6 many plants of a tenderer nature.

Hares-esr is a handsome shrub for the fouth front of

plantation;—fomewhat tender.

Honeysuckle, evergreen, allow it a sheltered situation,

and let it be as much as possible in fight.

Moon-trefoil is a very beautiful evergreen, flowering from May to October; but as it is tender, must have a try warm fituation, and then a little attention of cover in severe frosts may secure it.

Phillyrea in all its varieties, though rather a rambling grower, is confidered as one of the standing ornaments of our shrubberies; yet it has beauty in neither flower, for fruit, as is the case with some other plants, (partiiters ularly evergreens) being retained only for their foliage. The striped fort should have a sheltered situation, as alants, as their ornamental nature, in this respect, is win the consequence of hereditary weakness.

Periwinkle is a pretty under shrubby evergreen, if feed properly kept up to the lower part of pales, or a wall, feed the larger fort may be trained to a low stake, or wen kept as a little bush. It is very well to confine he roots (being apt to run) by flaty stones, or tiles:

fucceeds well in shade and moisture.

Purstane tree, the Spanish is not so hardy as the men mon fort, but will generally survive our winters, in good sheltered situations.

Ragment, this fort (as all the others) used to be four oufed in winter; but will stand abroad in a warm,

P 2

me

So

me

wh

dif

pe

oth lor this an for Till of wh

sheltered, dry situation, and its hoary leaves are very ornamental, though there is no great beauty in its flowers. When raised from seed, it is apt to get greener in leaf, and therefore it will be best raised from cuttings, which should be taken from the whitest plants. A likeness to original plants is frequently lost from seed, but is affuredly maintained from cuttings and layers.

Rose, this fort will need support, being rather trail

ing; train it to a sheltered wall.

Rosemary will not do in all situations. See page 256

Savin variegated leaved is very beautiful.

Smilax, as it is trailing, or climbing, is commonly planted to run up the trunks of trees, &c. It may be trained to tall stakes, and should be planted in sight, a in the front of plantations. There are several sorts of it, and the bay-leaved Virginian has black fruit.

### VII.

THE FLOWERS in the following lift of annuals are numbered (as the shrubs were) agreeable to their modular heights. The time of flowering is not mentioned, because that will vary, according to the time of sowing, management, and season; very sew before, a after June and July. Many of the sorts continual longer in flower than a month.

\*\* Some persons cultivate the serpentine cucumber, or melon, as a curiosity of the summer, the fruit being produced from one to two yards long, under good management; but it is to be remembered it will take up much room.

As to the *spirting* (or wild) cucumber, though it may be mentioned here, it is very hardy, so as to sow itself in autumn, come up in spring, and will abide as a perennial. Sow in *March*, and allow it two yards square. This is merely propagated for diversion; for if the fruit is touched when ripe, it bursts, and throws its fatid contents to some distance, perhaps over the clothes of the adventurer, and perfumes him.

#### OBSERVATIONS ON PARTICULAR FLOWERS.

Amaranthus, the tree fort, grows larger than the others, and bears purple flowers. The tricolor and bicolor are so called, from the former having the leaves of three colours; i. e. a bright red, yellow and green; and the latter of two, a deep red and purple; and it is for these, and not the flower, that they are cultivated. The flowers of the globe sorts have the peculiar property of retaining their form and colour a long time (years) when gathered. Clear the seed of this flower from its

downy covering before fowing, as a means of forward.

ing the germination.

Balfam, when double, and well marked, is a very fine flower. The plain coloured red and white, femidouble and fingle ones, are not of much account with the curious, but may be put out in ordinary borders to make a shew. The feed of this flower should be nicely faved from the fullest blossomed, and distinctly striped forts, that have not grown near small, or self-coloured fi ones. The plants selected for seed, should be protected from the wet and cold, after Mid-August, by putting them under lights, or in a green-house window, where they may have the full fun.

Calceolaria, the flower of, is esteemed only for the curiofity of its flipper shape. The blow may be con-

tinued all summer, by planting cuttings.

Capficums are usually ranked in the less tender class, and though they are in nature so, yet to have them fine, and to fruit in time, they should be brought forward, by being treated as ballams, &c. at least in fituations far north of London. They are grown for the beauty and use of their pods, which are variously shaped, as

long, heart, cherry, &c. See p. 248.

Cleome is a very tender annual, (has been long confidered as a flove plant), but may come under the cultivation of the ordinary florist, by continuing it longer in a frame, as suppose to Mid-July, or later, if the seafon is then unkind; and then plunging the pots in a When autumn approaches, a hand-glass warm border. may be fet on forked flicks over this, or any tender plant, and thus preferve it longer.

Colutea is a perennial shrub of somewhat tender nature, that hardly fucceeds abroad. Though the feed will come up on cold ground in high fpring, yet by fowing it as one of this class, it may be brought forward enough to produce its beautiful flowers the fame by autumn, See lifts IV. and X. In this last list it is confidered as a biennial, as it may be housed the first

ard-winter, and turned out into open ground the following

fummer, and fuffered to die.

Egg plant must have a dry soil, and warm situation, but yet plenty of water in hot weather. The blossom with s not striking, but the fruit is often as large as a swan's egg, and with common management will be as big as cely a hen's. This plant requires, however, to be sown fixed fit might be.

Sted Humble plant is one of the sensitives, the property of

the Humble plant is one of the fensitives, the property of thing which is to close its leaves, or drop them upon being muched. The common sensitive plant will grow to eight feet, in a hot-house, (which is its proper place) but the the humble plant is spreading, and seldom reaches more than a stature of two feet; for its lower growth it is therefore more proper for our purpose here. It is called: when touched, foot-stalk and all, as if making a bow. The humble plants are distinguished from the common ons upright growing fensitives, as the latter only closes the uty leaf, without dropping the stalk.

Ice plant trails and spreads wide on the ground, makes no shew in its flower, but is beautifully covered with thrystal drops, shining like diamonds when the sun is on it; or as the frozen drops of icicles. It is not nice in its culture, or weather, though it should not be put out too young. The best way is to plant one in a pot of fix or feven inches diameter, without any thing at bottom over the hole; and keeping it in the frame till it gets too big for the pot, plunge it in the ground a? little over the rims. Thus the plant will not be too uxuriant, but yet fufficiently nourished, (for it has small roots) and will flower sooner, and ripen the seed

better for this treatment.

Indian shot must be sown forward, and brought on by different hot-beds to blow the same year, being rather a tender hot-house perennial.

2 Sweet fultan, yellow, purple, red and white flowered 4 Tobacco, common broad and narrow leaved Virginian

3 Xeranthemum, or eternal flower, wh. violet and purp.

3 Zinnia, yellow few flowered, and red many flowered

The seeds of most of these flowers will come up in cold ground, (if not sown too early) but are forwarded by a little heat, so as to have them much earlier, and a finer blow, producing seed, which late plants will not. The forts that most require a little heat are, after, basil, geranium, love-apple, marvel of Peru, palma Christi, yellow sultan, and zinnia.

The gourd may be added to this class; but to succeed well, it should have a good south wall to be trained against, and it will take up a good deal of room there. Sorts numerous, as to size, shape and colour. The common pumpion (see page 237) is the hardiest; and the warted wange gourd is the prettiest.

## OBSERVATIONS ON PARTICULAR FLOWERS.

After, to come forward and fine, should have a second sight hot-bed to prick a few out upon, and indeed this would be a great advantage to any of the other sorts. These not thus forwarded, will make a second blow. The striped sorts are much the prettiest, yet the plain ones make a good shew, and do very well for shrubberies, &c. particularly the superb white and red. It is a good way to plant a few asters, or any slowers designed for seed, in beds by themselves, in a way of nursery, as in the best borders it is much neater to have all decaying slowers pulled off regularly, as soon as their beauty is over: Pull up all bad slowers (as soon as ever they are discovered) from amongst such seeding plants.

Balfam, yellow, or touch-me-not, is more frequently fown in cold ground, (as others of this lift, carthamus, cerinthe, Mexican poppy, princes feather, and xeranthemum) but it is worth while to afford the assistance of a little heat. This slower is sufficiently ornamental to

15,

ac

merit a place in the garden; but is chiefly curious for the elastic property of its seed pods bursting with force, when just pressed between the fingers, throwing the seeds to a distance.

Chinese hollyhock should be brought forward (especially northwards) to ensure a timely blow. See p. 280.

Chrysanthemum, to preserve some of the finest doubles, plant cuttings, or slips, the beginning of September, in pots, and house them before November, lest the frost come; and they will generally survive the winter, and slower much earlier, though not so strong as

those fown in spring.

Convolvulus major will need support by a wall, stake, or otherwise, to be trailed, or run up, as a scarlet bean. The deep blue fort is called convolvulus nil, or anil. The major convolvulus makes a good shew, and may be sown in April, in the places designed to slower; but it is the best way to sow three or four seeds in a small pot, which being placed on a gentle heat, will be much forwarder and siner, and may be turned out whole (when about three inches high) into open ground; for this slower (as many other annuals) does not transplant well: Nil will not do without heat to bring it up.

India pink is now brought to blow much more double and variegated than formerly, and it is a very neat, engaging flower, lasting a long time. Prick the plants out when quite small, (for they readily strike) that they may not be drawn up weak, and let them grow in single detached plants, in a dry light soil, and they will be strong. If cut down as soon as the principal blow is

over, they will fland another year.

Marigold, the African, grows strongly erect. There is a variety in the form of the flower, and the quilled forts are mostly admired. The French sort grows weakly spreading, but there are beautiful varieties of it from seed, which should be carefully saved from the most double slowers, having had no single ones growing near

near them. The smell of these slowers is unpleasant; There are sweet-scented forts of each.

Marvel of Peru is confidered as an annual, yet is naturally perennial in root—as our climate makes it annual. If the roots of those growing abroad are taken up in October, and dried a few days, they may be packed in dry sand, and kept in a dry place (from frost) till spring; when potted and placed on a gentle heat, they will shoot, and come forward.

will grow from seven to ten seet high, according to culture, as early sown, &c. As it is valued for its noble stature, and ample soliage, some gardeners bring it forward as a tender annual, in order to produce a giant; but it is not adviseable. The small leaved grows to about sour seet high, and is an agreeable plant

in the leaf, in other respects than size.

Nasturtium is impatient of frost; hence it has been considered in this class, to have it flower early. Late sown plants, if potted and housed, will blow in winter, and live round to spring. Cuttings of it will grow. The dwarf fort is preferred by some for flower borders, but is not so floriserous as the large. There is a double kind, see page 254.

Stock, ten week, (beautiful and fragrant) is the most important annual flower we have. Every one admires it, and its absence is always felt. It therefore merits every attention, to raise fine double flowers, to have them early, a continued succession, and as late in the

feason as possible.

There thould be four fowings of this flower in the year. Let the first be early in the spring, (as Mid-February, or beginning of March) on a gentle heat; and being soon thinned a little, they should be pricked out in about a fortnight upon another moderate hotbed, at sour inches as funder, where they may grow till this distance is thought too crowding; but the best rule is, to give them their final station as soon as they have acquired eight leaves.

The fecond fowing should take place on a little heat, when the first plants are pricked out; and let this fowing be presently thinned to an inch asunder; prick the plants out in the full ground, (or on a moderate hotbed, if you wish to forward them) at fix inches asunder. Here they may grow till either put out with eight leaves, or stand till their flower buds appear, which thew plainly whether they will be double or fingle; the double having full buds, and the fingle lank ones. But if every other is drawn with eight leaves, the reft will do the better, and may be taken up with large balls of earth; concerning the method of doing which, fee page 279. Or, every other being taken up from the bed, the rest may remain to make a grand shew in flower. All the fingle ones not wanted for feed, should be pulled, or cut up; then those left for the purpose will more certainly produce good feed, i. e. apt to come

The third fowing is to be upon cold ground, in a warm border, or rather under a hand-glass, the beginning of May. Let the plants be thinned in time, so as not to draw one another up weak, and pricked out at four inches, as soon as may be, as to showery weather, for stocks will safely transplant very young; and when they have eight leaves, let them be planted where they are to blow. It is a good way (in furnishing borders) to plant three or four stocks together, at four or five inches from one another, and those that prove single, may be cut out as soon as discovered.

The fourth fowing is designed for plants to be preferved through the winter for a spring blow, and should be made either the last week in July, or before the middle of August. Plant some close under a south wall, and pot others for housing in (only) severe weather. If two or three plants are put in a pot, the single may be cut away from the double as soon as dis-

covered.

The French stock is very floriferous, and most apt to come double. The Prussian is sometimes called the

fea-green flock, to diffinguish it from the others, which

are somewhat hoary leaved.

To fave feed that is most promising for double, mark those flowers which have five or fix leaves, by tying a bit of thread round them. A single flowering plant that has double ones growing near it, produces good seed; but those single flowers that come out before the double ones appear, it is proper to take off, as also all the late flowers, which if they ripen their seeds at all, would be weak; and a plant having but sew pods to ripen, will certainly produce the boldest seed, and of course the largest plants and flowers may be expected from it. Be sure that the seed is ripe before gathered, and that it is kept dry, in their pods, close tied in paper bags.

Sultan, the yellow is the finest flower, and has a very agreeable musky scent; but it is the tenderest, and will hardly do well without the assistance of heat to bring the seeds up: It will come, however, if sown under a small hand-glass, that is air tight, on a warm torder. The yellow produces much finer flowers, if

pricked out upon a fecond flight hot-bed.

Zinnia, the colours of this flower are dingy, but yet agreeable. Some gardeners chuse to treat it as the balfam; but a moderate hot-bed will produce the plants large and forward enough to ripen their seeds. Zinnia is, however, rather more impatient of cold than others of this class.

\*\* There will not need many observations on the sowers of this class. Directions respecting their cultivation will be found in the last section. It was there said, that May was not too late for sowing those annuals that come quick into slower:—the season may be extended (for late blows) to some, through June, or even the beginning of July, as annual stock, candy tust, convolvulus minor, rorn bottles, heart's ease, yellow lupine, mignonette, sweet-pea, and pheasant's eye. But, if dry weather, the seeds must be watered to bring them up, and the plants also to bring them sorward.

#### OBSERVATIONS ON PARTICULAR FLOWERS.

Belvidere is admired for its beautiful regular growth. The autumn fown feed make far the finest plants, and as felf-fown ones often come up, they should be preferved. This flower is adapted for potting, and thus it looks well. See pages 273, 281.

Ketmia, the flower fades in a very short time, when the sun is out; but the plant produces a great number,

in long fuccession.

Larkspur is seldom permitted to attain its utmost perfection, not allowing it room enough. The large forts should be from a soot to eighteen inches asunder, and the dwarf half this distance. See page 282. Pull

up all fingles. See page 59.

Mignonette is somewhat tender, and is often sown on heat, early in the spring, to obtain forward plants, for pricking out into pots, boxes, or baskets, to be housed in windows, &c. As it does not transplant well, take it up with a little earth about the roots; and, if convenient, put the pots, &c. on a little heat, till rooted. Summer sown plants, if housed in winter, become

Biennial; cut them down first.

Mulberry blight, or more properly blite; i. e. the herb blitum, whose fruit resembles a red unripe mul-It is also called frawberry spinach, from the leaves being like those of the prickly spinach, and the fruit like a scarlet frawberry. The plant must be supported by a wall, pales, or sticks, or the weight of the fruit (not eatable) will bring them to the ground. It looks best, and is very handsome, when trained, which it should be, just as a fruit tree, suffering no side shoots to remain on. The feed is near a month coming up, which makes autumn fown plants valuable, in order to have the fruit forward and fine. Some persons fow it in fpring upon a flight hot-bed, and prick the plants out where they are to grow; but to fow forward, in their proper place, (not to be transplanted) generally does very well; as it will then decorate the autumn, when other things begin to fail.

edging, or in little patches, will make a pretty early fpring blow, as it is very hardy: A light foil suits it best. This little flower is commonly spoiled by being suffered to grow thick, which makes it trail, and ram-

forward upon a little heat, will blow the same year, only later, as French boneysuckle, bonesty, scabious, senna, and stocks; but it is not generally desirable to attempt this, as they do not come so fine and strong, when made annuals of. Those just named, of course, though sown late the preceding year, will blow the next; but some of the biennials, in this case, will not blow the next year, as Canterbury Bells, a sew of which, though sown at their proper season, may stand over for the second year.

#### **OBSERVATIONS ON PARTICULAR FLOWERS.**

Campion, though a perennial, should be considered as biennial, in order to a timely supply; it sometimes is of no longer duration. The double (as bearing no seed) is propagated by slips from the roots; and it is a

very fine Flower. Pot fome.

Carnation is feldom considered as a biennial, though in fact it is so, as much as several others, usually denominated of this class; for, after the first blow, the plants become straggling, and slower weakly; it is, therefore, that they are always layered, &c. to continue them. The plain, deep red, or clove scented earnation, is the original, and an established cultivated fort. The rest are classed under the heads, slakes, bizarres, picquetees, and painted ladies, according to their colours, stripes, spots, and pouncings. For layering, and raising carnations, see the end of this section.

Chelone, the feed of this flower is best sown as soon as ripe, in autumn; and coming up in the spring, they may

may be planted in the borders, in June and July, and will flower the fame feafon?

Goat's Beard, the young shoots are eat (as those of

alfafy) like asparagus at spring.

Primrose tree, produces so immense a quantity of ked, that it becomes rather a troublesome weed to ome people. Cut the flower stems off, or pull up the lant, before the feed pods are ripe enough to shed heir numerous contents.

Rudbeckia, or American fun-flower, this biennial but is called hardy, but should nevertheless have a dry heltered situation. The narrow leaved dwarf perennial about three feet) sometimes proves biennial, and may ear, a sound extend their work in the culture of slowers.

Scabious has been noticed in the two last lists as an mual, which it becomes, if fown early; and fome ordeners make a point of doing it on a little heat to brward them. As a biennial, it should not be fown to foon; but if forward plants are transplanted in june, it will prevent their flowering till next year, then they will come very fine and strong, and this is he way to produce good feed.

Sena, bladder, or colutea, Ethiopian scarlet, is rather ender, and the feedling plants must be potted and ouled, or sheltered by a frame from sharp frosts. This flower is properly a perennial, (see list IV.) but sit is apt to be cut off in fevere weather, it is here onfidered as biennial, and may take its chance after be first flowering. It is sometimes made an annual of.

dee colutea, list VII.

Snap-dragon we consider as biennial, it not blowing handsome afterwards. The variegated (as all stripes re) is tenderish; this must be propagated from cutings, as indeed the plain may be, though the finest plants come from feed. This flower is of longest coninuance in a poor foil, and will grow and flourish out. of cracks in old walls.

Stock, or stock gillistower, is apt to get too rampan ing (in some seasons) before winter, and when killed by frost, it is chiefly owing to this circumstance; for no thing stands severe weather well, that has grown very freely. Hence it used to be the custom of florists to transplant them several times in the summer; (even a bea every full moon) but to keep them down, and hardy this by this means, tends directly to weaken the blow, i orn by this means, tends directly to weaken the blow, i orn not to kill the plant. The most reasonable method i method is this business is, not to sow too early, (or before the sout in time, that they may not be drawn up long die legged; and by no means to let them have a dung we consider the sout in time. foil to grow in, or a very rich one. Prick them ou the first cool weather after they have fix leaves, at so but or eight inches asunder, where let them remain til to August, choosing a showery time, (rather about the Ju middle) to plant them out where they are to blow but let not this be into a moist foil, or damp situation It is a good way to mix half sand in the mould that lies about the shanks above the roots; and when we and frost comes, to lay coarse, or drift sand, roun about them, three or four inches high, which remov at fpring. Some of the weakest plants may remain i the nurtery bed till fpring, which put out in cool ground for in such a soil they blow best, though they do no stand the winter well in it: Stocks blow much fine in a showery summer that in a hot one. It will be a great advantage to those moved at spring, to have balls of earth to the roots, though they do not we retain it. To dispose them to it, and make them fitted to transplant, they may be cut round in autumn, wit a long knife, five or fix inches deep, and about thre inches from the stem, making one slanting cut unde the root, at fix inches depth, to cut those alunder that strike directly down. This is a practice that would answer in most things that are to be removed at spring and if not, it would generally be of service, as the cut in tin

XIX

npan

we oun nov in i

ound no

fine ILb hav we fitte Wit thre inde tha oul ring cut tin

ing off the end of a downright root, occasions it to hrow out feveral others of a more fibrous nature.

Sweet William (or bearded pink) is distinguished the per into broad and narrow leaved forts. This slower that to broad and narrow leaved forts. This slower that the many plain, others hardy thirty or forty. But the single ones are generally so ornamental, that the want of doubles is not much lated in mented. The double sorts are propagated from layers, as carnations. The sweet William is perennial, but then as the plants cease to be handsome (and in some cases long die) after the first blow, it is necessary to raise some wery year for ordinary use.

Wall-slowers, raised from seed, produce some doubles; the first but the chance is not great for sine ones, which are Sweet William (or bearded pink) is diffinguished

the but the chance is not great for fine ones, which are to be continued from flips or cuttings in May, June, of the July: plant them in a rich foil, and shade till rooted. The double white wall-flower is tender, and should be tion potted for housing, as indeed other good forts of this flower should be and generally are

## OBSERVATIONS ON PARTICULAR FLOWERS.

Acanthus, or bear's breech, is admired for the elegance of its leaf. It spreads wide, and should have nom allowed it, in a warm light soil, and sheltered stuation; but still rather a shady, than a sunny one.

Alyssons do best in a dry hungry soil, but should have a favourable situation, where they will blow

ong and prettily.

Avens will grow in any cold moist shady ground.

Auricula, from the great and elegant variety of its lower and leaf, arising perpetually from seed, is one of the florist's chief delights, and to which he pays such attention in the culture. It is one of the first lowers, and ranks in nature with the primrese and countries. The sorts admitted in the present collections.

tions, are about four hundred. The auricula, the carnation, tulip, hyacinth, ranunculus, anemone, &c. are called fancy flowers. For the propagation and culture

of the auricula, fee the end of this fection.

Bear's ear fanicle is very hardy, yet being low, is a proper plant to pot. It may be planted in any cold place, and should have a dry lean soil, but be duly watered in summer; and most things that a poor soil suits, must still have water freely in warm weather. This sanicle is about six inches high; that of Gmelin only sour.

Betony, as a native of the woods, is proper to plant

in shrubberies, and shady places.

Birth-wort is tender, and feedlings of it must be sheltered by a frame in winter.

Bryony is a climber, and is proper to grow in planta-

tions to run up trees, &c.

Campanula, pyramidal, may be propagated (as well as from feeds and flips) by pieces of its root, planted about an inch and half in the ground, in a shady, but not moist border. The finest plants are produced from feed; but will be three or four years before they blow. Sow a few every year in April, in a light fresh soil, where the morning sun only comes. As much wet in the cold seasons is apt to rot this root, it will be proper to guard against it, by some occasional covering, when there is a continuance of rain, or snow. A few potted may be removed under shelter. A mass set high over is a proper covering for a bed of them. In the summer they must never want water, especially when spindling, or in blow. There is a white fort.

Cardinal flower must have a dry soil and a warn situation; occasionally also a little protection. The are commonly potted, and some should at least be so lest those in the open ground be cut off: This flower is very ornamental, but the scarlet most so.

Christmas rose is very hardy, but a dry warm situation may be allotted it; and when in slower, a little protection

e so er i

littl Aiol protection to preserve the flowers in beauty, as a bandglass may be adviseable. A plant or two potted (large pots as it spreads) is agreeable enough, at such a season, to house when in blow.

Columbine comes in great variety, and the feed should be well chosen, which, when sown in spring, is rather apt to miss. Autumn is therefore preferable; and these plants will from this sowing be much stronger. The plants should not stand above two years after slowering, as afterwards they get unsightly, and plain.

Cowship American is commonly potted, as indeed some plants should be, as it thus appears to advantage; but it is hardy, and grows best in borders that are somewhat shady, not having the afternoon sun.

Dragon's head should have a moist shady situation.

Figwort, the plants are somewhat tender, and may be only expected to stand through ordinary winters, in a warm soil and situation. Let some be potted, for housing, lest those abroad be cut off.

Fox-gloves do best in a somewhat strong soil, and shady situation, and will be sound a useful slower in

shrubberies, &c. in all its varieties.

Geranium, (or crane's bill, so called from the shape of the seed vessel) the exotic sorts are tender, Africa being their native climate. As favourite flowers, the different sorts are cultivated by all descriptions of people, as opportunity affords to preserve them in winter. They are properly green-house plants. The principal kinds are as follow, classed according to their ordinary height of growth:

I. Flaming, or Vervain mallow leaved, scarlet.—
Three coloured; i. e. red, black, and white.—Ladies mantle leaved, whitish and bluish.—Sweet-scented mallow-leaved, white.—Gooseberry-leaved, reddish.—Caraway leaved, or variable geranium, red, crimson, purple, white, &c.—Vine leaved, red and white.—Night-smelling, yellowish with dark spots, three sorts.—Pinnated, or proliferous, of different colours.

i

V

h

1

b

n

1

2

b

8

u

8

2

n

2. Spear-leaved, white.—Fleshy stalked, or celandine leaved, white.—Square stalked, slesh coloured.

3. Birch-leaved, reddiff.—Sorrel leaved, blush, plain and striped flowered, and variegated leaved.—Three gouty stalked, or columbine leaved, purple.—Rose-scented, a purplish blue.—Glutinous vine leaved, reddish purple and white.—Horse-shoe, green leaved, variegated, silver edged, silver striped, gold striped, pink, two scarlets and a purple, and one large scarlet, or grandissorum.

4. Vine-leaved, balm-scented, blue.—Shining, and mallow leaved, scarlet and deep scarlet.—Buttersty, or variegated slowered, with a pointed mallow leas.—Marsh-mallow, or hood-leaved, purplish; and a variety of this with angular leaves.—Rasp leaved, sless colour, spotted red.—Two coloured, purple and white. See

the end of this fection.

Gentianella likes a cool loamy foil, and eastern fituation, and should not be often removed, or in too small

pieces when it is.

Globe flower, or globe ranunculus, is very ornamental. The European is sometimes called locker gowlans. They both do well in a cool soil, and north border; though the name Asiatic seems to direct to a dry soil, and warm situation. The case is, they are natives of most, shady places; and whenever this is the case, we may conclude such plants are organized accordingly, and that they must be accommodated by us agreeable to their nature. The constitution of plants is necessary to be known, in order to their proper culture; and a gardener cannot direct his attention more to his credit, than to make observations and experiments to discover it.

Golden rod will grow in shade, and particularly the evergreen fort; but being late blowers, this circum-

flance directs to a foug sheltered situation.

Hellebore, the white flowered, is the common officinal plant. A light foil and dry fituation, not subject to suails, suits it best.

Helonias is a very elegant and ornamental plants worthy of the most conspicuous part of the pleasure garden. It requires only the ordinary culture of perennials. Seeds are imported from America, as the climate does not ripen them here.

Hepatica is found to transplant best when in flower; but it should never be in small portions, lest it wither away; they never look well in small patches, as is the case with all dwarf blowers. Situation and soil the

fame as gentianella.

Ladies smock, and ladies stipper, do best in a moist soil and shade, as in a north border, where not many other things do well.

Lily of the valley should have a cool situation, and if not in a moist soil, give it at least an east border, or

where it has only a little morning fun.

Lion's foot is somewhat tender, and to do well must have a favourable place in the garden, as to sun and shelter; it does best in a light, or sandy soil. Let some be potted, it is pretty, and blows all summer.

London pride (a faxifrage) used to be planted much as an edging; but it does not answer this purpose well. A few plants here and there in parches is best; by no means allow it a good border: It prefers a moist soil

Loofestrife, the common, is found wild; but it is a showy plant, and where a variety is wanted is very admissable. It grows in shady moist places, and should be planted accordingly, in the borders of a shrubbery, &c. The smallest fort is a trailer.

Lupine will be best raised from seed, without transplanting, as the roots strike down deep: If they are transplanted, let it therefore be quite young.

Lungworts prefer a shady situation; but the Virginian (an elegant little plant) rather one that is dry

and sheltered.

Lychnis, the double scarlet is a beautiful flower, but not apt to encrease much at root; recourse is therefore

to

edg

foil

wh

to be had to cuttings, which also are not certain but striking root. In June, or July, take cuttings from for the fide shoots, (without flower) and let the piece planted have three, or at the most four eyes. Pland them into a good foil, fine and rich, but not dung as deep as half way between the second and third join in an east border: and keep them cool, but not we A hand-glass will greatly affist in this business, as i all other like cases. See pink at the end of this section The Chinese lychnis is rather too tender for open cu ture; but in a choice fituation may abide moderate win ters. It makes a good potted plant among myrtles an geraniums.

Lychnidea, take the cuttings off close to the ground and discharge the tops; and plant them in pots, o

borders, in a place not of much fun.

Master-wort (a medicinal plant) is of no great or nament; but is commonly cultivated for borders of thrubberies, &c. as being of low growth, and hardy nature. There is an alpine fort about a foot high.

Marsh marigold is a plant (as its name imports) that will flourish in a wet soil; but yet it does not do much amis in a dry one. In default of a moist soil, any plant that requires one, fhould at least be accommodated with a fhady fituation, and never want water in fummer.

Milk vetch is somewhat tender, particularly the feedlings, which should be protected by a garden frame in winter. Fox tail fort, see biennials.

Monkey flower is very ornamental, and of easy cul-

ture, not difficult in fituation.

Monk's hood is a poisonous plant in every part, but very ornamental, and commonly cultivated. Shade fuits it, and it will even grow under trees, or in any damp place, where few other things will.

Morina is worthy of a conspicuous place in the garden. It has a strong tap-root, and should be transplanted whilft young, that it may not be damaged; but piece

111

tain ; but fowing in the place where it is to grow (as directed for the lupine) is the best way.

Mulleins prefer a light foil, but like a north border; Pand the borage leaved being very low, is proper for an. dung edging in a cool shady siturtion.

Orpine, this, as all succulent plants, should have a dry

foil and fituation, and not often watered.

we Passion flower should be planted against a warm wall, where it may have room to spread, as it is a very free ction shooter. The forts are numerous, (for green-house 1 Cu and stove) but only this well fuits open culture. Inwin fine fituations, and the fouthern parts of England, there: are two more, however, that may do abroad. Prune: it about Michaelmas, leaving the shoots from two to four feet long; as the strength of the plants, or room, dictates, and a foot afunder. Before the frosts come, cover the roots, a yard round, with dry litter; and renew it with dry, when afterwards it gets much and The branches also should be covered with long wet. a mat (a thin one, and not over close) before fevere frost sets in; but uncover as soon in spring as may be or, in short, in mild weather, on days through the This flower haswinter, if not too much trouble. been fometimes trained to a stake, in which case, shorter pruning must take place to keep it down. It bears upon the young shoots, which should be regularly trained in. The flowers are the glory only of a. day, but generally a great number are produced in fuccession. It takes readily from cuttings, of about seven or eight inches long, cut in March or April, and planted in a good foil, kept cool by water, and shaded from much sun.

Pink, the forts are numerous, for feed is constantly producing new varieties, occasionally one among many. that vies with its famed predeceffors in beauty, and whose superior excellence is not neglected by the florist. He gives it a name as fancy directs, and it is enrolled. in the nurseryman's catalogue of worthies. The pink: (as the carnation was) might be confidered biennially, the good forts being regularly layered, &c. every year:

1

for increase: They do, however, stand on for older plants, better than carnations. For propagation, &c. see the end of this section. There is a pink called the ever-blooming.

Polyanthus produces an infinity of forts from feed, and the florist pursues his object of obtaining prize flowers of this kind. The polyanthus delights in a loamy foil, and shady situation. It is an excellent edging flower for shrubberies; though fine blows are not to be expected under trees, or in much wet. An east border is the place for producing the best flowers. For raising them, &c. see the end of this section.

Plumbago, though it be a native of Italy, is hardy enough to abide our ordinary winters in the open ground. Afford it a dry, sunny, sheltered situation, which will be a means of preserving it, and also tend to forward the blow, as it is so late: All plants that produce their flowers towards the end of autumn, (however hardy) should have a favourable aspect, as to sun, lest winter overtake them before they can gratify us with their show.

Poppy, allow the eaftern fort a light dry foil.

Reed, Portugal, is curious for its lofty and ample growth, but rarely flowers with us. It attains to ten or twelve feet high, and its stems are strong enough for walking-sticks. The variegated forts come only to half the size, and more frequently flowers.

Rhubarb, the common serves for show, and the ribs of the leaves for tarts; but the Chinese principally, and then the Tartarian for medical uses of the root: The Chinese is deemed the true officinal rhubarb.

Rocket, (sometimes called dame's violet, and queen's gillissower) the single is raised from seed, and the double from rooted slips and cuttings. The double is rather uncertain in continuance, and requires some attention. Cut the stems down as soon as off their principal show of slowering, which is a means to help them to get strong and encrease at root; and it is from offsets formed

der &c. the

IX.

rize n a lent

An ers.

rdy pen on, end hat

nn, to tify

ple ten igh nly

ibs ly, ot:

n's ble ner

get ets formed in the present year, that they slower in the next. If weak, or small roots are planted, they should not be suffered to blow the first year. To propagate by cuttings, do it when the stems are about eight or nine inches long, (i. e. before slowering) making each into two; and plant them a little more than half way deep, in an east border, in good fresh undunged soil. Keep them cool by occasional watering, and if the cuttings attempt to slower, be sure to nip the buds off. Cuttings of stems that have slowered, will sometimes grow, but they make weak plants: A hand-glass would be of service over them. See pint at the end of this section.

Rudbeckia, or American fun-flower, is a little tender, and must be accommodated accordingly. Like the rocket, it is rather (some sorts at least) unapt to form offsets; and therefore to encourage the putting them forth, (without which the plant dies) the stems may be cut down to prevent slowering: That is, when plants are more defired than slowers.

Rush will be proper only for places that are conflantly wet, by standing water; and in such a situation

they will prove ornamental.

Sarracena is a native of the bogs of North America. It requires therefore a moist fituation; but is found to need protection from our sharp frosts. The whole plant is of curious formation. It is not apt to ripen its seeds here, or to make offsets; so that both are frequently imported.

Saxifrage plants are usually potted to move into the house when in flower, as indeed the pyramidal in particular should be; but they are all very hardy, except the strawberry fort, (not very handsome) which is too

tender to endure much wet and cold.

Senna, of Maryland, must have a dry soil and warm situation. It is annual in stalk, and therefore the roots may be well protected in winter: This slower makes a very handsome show.

Solomon's feal is in greater variety, and there is one with double flowers. They all fuit well in shady and moist places.

Starworts are in general of that hardy nature, that they will flower almost any where, and increase apace from the least slip. They are apt, however, to lose their lower leaves, in proportion to the shade, cold, and wet, they grow in; and the Alpine fort will require an open situation, though, like the others, a stiff moist soil suits it. There are other forts. The three last, as blowing late, and not rampant, may be planted near the house.

Stock, this plant is rather of a biennial nature, but generally of longer duration. It is proper to pot and place in a window, on account of its fize, rifing only a few inches. It is fweet and floriferous, and altogether very proper for an edging.

Sifyrinchum, allow it an east border, but dry soil;

and as it is a finall flower, pot some.

Throatwort, the two first sorts are classed with campanulas. The latter, which is the proper, or mountain blue throatwort, likes the shade, but must have a light dry soil. This, as the snap-dragon, and some others, will grow in the cracks of walls, &c. and continue longer in such a situation, than a better: In most soils it proves often biennial.

Whitlow grass is a wild (medicinal) herb, that grows on roofs and walls of old houses, and rubbish heaps; but makes a pretty dwarf spring slower as an edging,

&c. in a poor foil.

Worm grass is a very neat little plant, with a flower bright red without, and a deep orange within.

by offsets, or pieces of roots, having an eye, or bud, to it. Most of them may be raised also from feed; but this is a tedious method, and not ordinarily practised, except by

curious florists. See page 284.

Some of this lift, as most of the bulbous and tuberous roots, may be kept out of ground a long time, others a shorter; (see page 286) but those denominated steps roots, must either be planted immediately, or at least in a few days. It is common to them all to be taken out of ground for removal, as soon as their leaves decay, the roots then being in a state of rest, which is naturally longer, or shorter, in different plants; and if they stay in the ground till new sibres are shot, they are always removed with damage, if not death.

# OBSERVATIONS ON PARTICULAR FLOWERS.

Albuca is too tender a bulb to endure much wet and frost, and therefore is usually planted in pots, for putting under shelter (as in a frame, &c.) in winter; but may be protected in the open ground, by covering with a glass, or garden-pot, towards the end of autumn, to keep

keep the roots dry; and before sharp frosts come, covering round with litter. By such a practice, several sorts of tender things that die down to the ground, may

be preserved abroad.

Anemone, the garden (in contradifinction to the wood) we have in great variety of very fine forts, divided generally into two kinds; i. e. narrow and broad leaved; the latter is the hardier. The full doubles only are esteemed choice flowers; but the semi-doubles, and singles, are showy enough for ordinary borders. See 290, 293. The single, or poppy anemonies, (so called from their form) frequently blow as early as February, or sooner: and thus become valuable, for decorating the ground at so dreary a season. The wood kinds bear large flowers; and are very useful ornaments for the borders of shrubberies, &c. at an early season, for which reason, they should be planted in the most frequented shady places.

Colchicum, or meadow saffron, flowers about Michaelmas, and may be kept out of ground from May (or decay of the leaf) to Mid-August. It is a remarkable property of this flower, (not however peculiar to it alone) that it makes its appearance before the leaves, which grow all winter and spring. The colchicums are pretty plants for the end of the flowery season, (October) which makes them estimable objects near the house, where they may be often seen. The flower sometimes called spring colchicum, is the bulbocodium,

which fee.

Cyclamen, the forts flowering in winter (Persian) are too tender for open culture; but close under a warm wall, with occasional protection of a hand-glass, they have succeeded. A culture of this nature is rather to be attempted, as housing (except in places where they have much air) does not suit them; the roots often moulding and rotting when kept close. The colours of the Persian sorts are red, purple and white. Let them have a light, and deeply dug dry soil, not too

much water, and none at all after the leaves begin to decay; for the roots then ceasing to act, would suffer by absorbing much wet, the leaves not performing their office of drawing it up, and discharging it. This observation applies to all bulbs and tubers, (in a degree) though few are so liable to rot as these.

Fritillary is of several colours, plain, chequered and spotted, white, purple, black, red, and yellow. The kinds are broad and narrow leaved; and there is a large double sort, a tall Persian, (three seet high) and a dwarf Persian, about half size, both having deep pur-

ple flowers.

Jonquil, or rush-leaved dasfodil, has been always justly admired for a very neat sweet slower; but we do not so often meet with it, as might be expected. The single kinds are the most fragrant, and the large double is scentless. It is proper always to pot some, in order to bring them into the house when in flower, for their agreeable persume.

Iris, the four first forts rather prefer a shady moist situation; but will grow any where, and are commonly

planted in odd spare corners of ground.

Ixias are, for the most part, green-house and stove plants; but these two sorts are found hardy enough to do ordinarily in open borders, in a light dry soil, and warm situation, a little protection being afforded them in severe weather.

Lily is a very ornamental and hardy flower in all its varieties, encreasing abundantly, and needing only to be removed every three or four years, for the purpose of taking away the offsets, and renewing the soil for a superior blow. The whites will not keep out of ground above one month, but the orange for several. The white will flower tolerably in shade, but the orange much better; and as it is a gay flower, it serves well to enliven plantations. The martagons are generally not nice as to soil and situation; but the scarlet and yellow sorts, and striped lily, should have a light dry

fail

foil, and fun. The fingle white lilies are very sweet; but the doubles are inodorous, as is the case with some other flowers, the fragrance arising from the stamina and anthera, which are often finothered by numerous petals. The Atamasco, Guernsey, belladonna, and pancratium lilies, are tender, and should have a warm, or a good auricula foil, a full funny border, and well sheltered lituation; protect also from much wet in cold feasons, and afford fecurity from frost. These are very elegant and noble flowers, and the Guernsey lily is equal to, if not beyond, any plant in the flowery creation: This is, however, the tenderest of the four: then the belladonna, and pancratium lily, or fea daffodil; the atamafo is the hardiest. All of them are usually potted for removing into shelter; but they may be managed (see albuca) fo as to do abroad, except in the more northern and bleak parts of this island: They blow much the finer in open ground, (all things going on well) the toots having a free scope to draw nourishment, &c.

Orchis is rather difficult of culture: It likes a dry barren foil, and the roots should be taken up (from the places it grows wild) just as the leaves decay after slowering; and with a ball of earth about them, as then the chance of succeeding is much greater. Upon removal, let them be planted directly, and remain in

their places for years.

Preony, the fingle kinds are showy, but the doubles are nobly ornamental. Let this slower have room, as it will spread (when in full sized bunches) a yard round: and let it be planted out of the way of the full sun, and of much wind, that the slowers may continue. It need not be removed for many years, and will grow in any soil and situation, even among trees, which adapts it for shrubberies, &c. The forts are divided into male and semale; and the former, having lost its slower, produces pods, containing rich crimson grains, interspersed with black berries, that look very pretty when burst; and may be gathered as soon, or rather

an

ea

m

just before they open, brought into the house, and put in vials, &c. as curiofities. Let this root be removed early in September, or at least before the month is out, before new fibres are formed to the knobs of the roots.

Pilewort, (the double) prefers a shady moist situation; and is a pretty wild plant, though an humble trailer. It is called sometimes the lesser celandine, and also figurest erroneously.

Ranunculus, in all its forts, is very ornamental; but the Persian kinds are beautiful, and of infinite variety. This flower is furely left too much to the culture of professed florists; for why should not every garden be adorned with it, seeing, that a little care, and not much skill is necessary in the management: it is hardy and encreases freely. See pages 285, 288.

Saxifrage roots of the double forts are like fo many fmall peas, and should be planted five or fix together in order to form a full tuft of its flowers, which are full and white like a stock. The stems, being slender, will need the support of a light stick, which it is best to fix in the middle at the time of planting, as putting one in afterwards might injure the roots. All folio rooted plants are liable to be hurt by pushing in a stick too near for tying to; more care should be taken in the business than usually is: The practice of placing a stick at the time of planting is best, because it may then be fixed close; and it ferves to show where the roots are that they may not be disturbed before they appear above ground. This faxifrage is usually and properly potted though it does very well in borders, and makes a good appearance.

Spider-wort thrive's best in shade and moisture.

Star of Bethlehem, the two last sorts, are proper for the edges of borders in plantations; and the pyramidal fort is a proper flower to pot, mixing with others very ornamentally: The two first should have a light dry soil, and are somewhat tender.

dry

Squill will need a little protection from hard frosts; but is sufficiently ornamental to reward the trouble.

Tooth-wort thrives best in shade and moisture.

Tuberose, there is a dwarf stalked, and a variegated leaf fort of, but they are not so worthy of cultivation as the common single and double; of which two the single is preferable, as it blows better, and is more

fragrant. See the end of this section.

Tulip (the Turkey) is classed into two forts; the taller, ealled ferotines, or late blowers; and the shorter, pracoces, or early blowers; some have made another distinction, medias, but it is not necessary. The plain tulips (as they generally are when they first blow from feed) are called whole blowers, or breeders; and according as they break into other colours, stripes, and variegations, (after transplantations) are denominated and classed into baguettes, bybloemens, verports, and bizarres. The dwarf forts blow early, as March and April, (the duke van tol earlier) allow them therefore a warm border and dry foil, to preferve them from frost and wet, which they are rather impatient of. These are often potted and forced on a hot-bed, &c. or brought forward by water-glasses, in a warm room; but an increase of offsets, is only to be expected from open ground culture, and even there these early forts do it sparingly. Take them up every year to remove the offsets, and renew the foil; and keep each fort separate; and plant them fo, for then they will blow together, and be all of one height. There are about fifty of the early forts; but the number of choice fancy tulips is more than eight hundred.

THE following articles are detached as most con-

Auricula is increased by parting the roots, or flipping rooted offsets from them; but offsets without

roots will fometimes strike, if well managed, by fetting them in a good foil, (in pots best) where they have but little fun, and keeping them cool by occasional When the roots are divided, (in August) let it be with a sharp knife; and cutting off any cankered part, shorten also their ends, and let not the tab part of the root be too long.

The foil for auriculas thould be a good fresh light loamy maiden one, to which is added one third of wood pile, or willow earth, one of fea, or any sharp, or drift fand; and a quantity, equal to the whole, of rotted cow dung, or in lieu of this, horse dung. This mixture should be well incorporated, at least a year before, by frequent turning over, which ought to be repeated once a month without fail.

In winter some protection is necessary; but auriculas are not very impatient of frost, which rarely hurts them if dry. Do not follow the custom of some persons, who lay the pots on their fides in winter to keep them dry, and to cover with straw, &c. For a short time about Christmas it may be allowed; but soon after, as they begin to ftir in the shoot, it gives the bud a twist, if they remain long in this posture. The best way to guard from fnow, wet, and fevere frost, is either by frames, or plunging under a fouth wall. Place a bit of tile at the bottom to keep out worms; and if the foil is moift, lay fome drift fand, or fine ashes round their fides, and over the tops.

Dress the pots towards the end of January, for then the plants begin to push for flower, and must be attended to, and affisted. Strip off dead leaves. Take as much of the top mould off as can be, without diffurbing, or bruifing the roots; and fill up with the compost, a little pressed down. If the pots are dry from the shelter afforded them, give a little soft water in mild weather, about ten in the morning, and fail not to

water duly, as the plants puth forward.

Auriculas

fet. Auriculas in blow should be protected from rain, hey wind, and sun, and their stems supported by little neat small sender formed sticks, or strait ones, and tied with shread; and when out of blow, should be set out of the san-sun, but not under trees.

Shift or transplant auriculas every second year, and

that as foon as they are out of blow; those, however, hat produce many offsets, or are luxuriant growers, may be shifted every year. The more common practice is to move all in August.

To raise auriculas from the seed, in February, fill by mooth the top perfectly level; featter the teeds evenly, ace and cover not more than the thickness of a shilling. set the pots, &c. on tiles, or boards, under a warm wall, and keep the furface moift. It is a good way to mix the feed with a like quantity (or a little more) of fine wood ashes; and to lay some small pieces of furze, or light thorns over. Remove them (as weather dictates) ofhelter, or protect them from cutting wind, much frost, or heavy rain, &c. and by May expect them to appear, when take the furze off, and cover with a net; let them have only the morning fun, keep them moist, and when they have got fix leaves, prick them out three inches afunder, in boxes, or pots; and early in the next pring, plant them at fix inches afunder, and protect from wet and frost.

Carnation is usually propagated by layers, (fometimes by pipings or cuttings, as pinks) about Midfummer, or is foon after in the feafon as they will admit of it, by their length and strength, and the work is thus: Strip off the leaves from the lower part of the shoot; at the middle of it, close below the joint, cut it half through by an upward direction, with a thin, narrow, harp knife, and continue the flit exactly up the middle from half to three fourths of an inch; peg the shoot down into the earth (being before well loofened) as low as it will bear bending, fetting the layer upright.

SEC

thr

giv

the

ove

W

for

the

fha

wir

See

ling

lay

feed

This business must be done with a careful hand, lest the layer should snap off. Now, or rather before, cut off the ends of the longest of the top leaves, that the worms may not draw them them in, and disturb the layer. The foil (fine and good) may be raifed about the layers as occasion requires. Water them to fet the earth close, and always keep it cool. In fix weeks, or two months, they will be rooted, fit for transplanting; cut them from the old plant (at the peg) with a sharp knife, and take them up carefully, that their very tender roots may not be broken off, keeping a little mould about them, if possible: but plant them not deep, as

they are then liable to decay.

The foil proper for carnations, is a hazelly, or fandy loam, procured from a pasture, by a spit of about eight gro inches depth, the turf being well broke, frequently thir turned, and laid so long together, as to be nearly confumed; then add a little lime, (or not) and one third, it is or one fourth, of very rotten dung, (cows best) and let this be well mixed, till thoroughly incorporated, which will be some months first; then screen it, or sist through a coarse sieve. The soil for carnations must kee be rich; but yet dung is found so injurious to carnations, that some florists depend upon a good fresh soil alone; carnations are also (except in summer) impatient of much wet. See to them in the winter and give pots of them protection from great snows and frost, by frames, or mats on hoops, set rather high. Turf ashes, or those of any vegetable, may be mixed with a fresh maiden foil, but not too freely for a compost: A small quantity on the soot, or wood ashes, may be also used. Dress that so of carnations in March, as directed for the auricula. The foil proper for carnations, is a hazelly, or fandy ricula.

To raise carnations from seed, sow thin in boxes, teat or pots, (in a soil as above) early in April, and let plan them have only the morning sun. When advanced a little in growth, (as about Midsummer) take the first bree opportunity of moist weather, and prick them out at three

IX.

left

the

out the

or

ng;

arp en-

uld

ght

itly

three or four inches afunder, into open ground, and give a little water. If dry weather, contrive to shade cut them about ten days, or a fortnight, with mats hooped the over, which remove in shady, or showery weather. When they have grown here a month, or fix weeks, for before August is out) plant them in a bed, where they are to blow, at nine or ten inches distance, and hade, if necessary. Protect them from much wet in winter, and in hard frost, by mats, or hoops, set high, See January. Seed is best faved from good seedling plants, rather than those long propagated from

layers, &c.

Geranium, African, (Pelargonium) is propagated by feeds and cuttings. The former produces the most free growing plants; but as luxuriance is not defirable in things confined to pots, (as geraniums must be) and as the propagation by cuttings is so easy and expeditious, it is the mode of culture that generally prevails. The young plants from cuttings are also hardier than those from seed. If raised from seed, sow in April, in a light and good soil, warm border, and under a hand-glass, the the of a gentle hot-bed, giving plenty of air to the plants, when they appear, which on natural ground will be five or fix weeks in coming up, and on a moderate heat about three. If raised from cuttings, use shoots of the last rear's growth, strait and short jointed. Plant them in a fine rich soil, two or three inches, or at the most source, and eight or nine inches assunder, or less, if more town the soil three in the ground be deep as some people do. Those raised on a little week, leat will be sufficiently rooted in two months to translate that into small pots; (shortening the longer roots a lattle) and those in the cold ground will be ready in three months, and sometimes less. A hand-glass set were geranium cuttings (or any other) will greatly saches. things confined to pots, (as geraniums must be) and as

cilitate the business, as is directed for pinks. If the cuttings are raw, or long, take the upper part off down to an eye. In general it may be proper to keep the cuttings out of ground a day, or two; but the foft and fucculent ones should by all means, in order to dry the ends, and so heal the wound, which, if put directly

in the ground, might decay and rot.

The proper feason for planting is from Mid-May to Mid-July: a little earlier, or later, may however do: Some chuse to forward them on heat, in March and April; but they must not be kept close. It is adviseable to take cuttings from towards the top of plants, in order to keep them down; but where they can be belt fpared (as to the form of the plant) is the general rule. Pot them in August or September, according to the time the cuttings were put in: The former time is much the best.

The management of geraniums is, to keep them from frost, and as much as may be from harsh winds, particularly in the spring; as after being housed all winter, they are then tender, and far less able to bear unkind weather, than in autumn; when having been used to the external air, and the colder weather coming on by degrees, they are feldom hurt much but by absolute frost. In the spring, they must be brought to bear air by degrees, and the more carefully. according as the winter has occasioned them to be more or less deprived of the external air, being let in upon them. When the weather is mild in April, le them be taken out in the day, (if convenient) and put in on nights; and venture them not wholly abroad till Mid-May, or after. In the fummer, they should be sing placed in shelter and shade; but not under trees, or any more of it dries the mould in the pots too fast, and fades the slowers. They will want frequent watering fee page 277. They may take up their fummer refidence about Mid-May, (as directed) but the feasing form roof: The morning fun is all they should have, for

must govern; and it will not do to bring them out in a harth one, which would pinch up the leaves, and deprive them of their beauty. If put close under a fouth wall for a week or two at first, it would be proper; or an awning of mats might be used for nights.

Shifting geraniums should generally take place once a year, from smaller pots into others one fize bigger: This may be in the first mild weather in April, or May. Loosen, and take off the top mould down to the roots, (without damaging them) then turn the pot up, and shake it out. If the roots adhere to the sides of the pot, give the edge a tap upon the knee, or fomething elfe, and a little pressure at the hole, with the thumb, or finger, at the fame time, which will help to discharge it. Pare off the matted roots round the fides and bottom, with a sharp knife; and plant it in a fresh pot, (or the same again may sometimes do) putting in as much fine light rich mould, or compost, at the bottom, as will raise the ball of earth, which is about the roots, within an inch of the top of the pot; then fill round the fides, putting the mould by little and little in, and preffing it down gently, make all level to the top within half an inch; finally, give a watering that shall soak to the bottom, and fprinkle fome dry mould over: All shifted plants should be kept rather in the shade for a week or two till rooted.

If any fliks are to the plants, they must be taken away first, and replaced (if necessary) again before watering, or rather the next day, if the plants will stand up without. This may be a proper time to trim off all dangling, or too crowding shoots; but if cuttings are wanted for encrease, they should not be trimmed till these are to be planted. At any rate, dead leaves, or unsightly crocked parts, should be discharged, and symmetry, in a snug round head, provided for.
Geraniums are free growers, and it is always adviseresiduated to take off some shoots to keep them down and in must show that most need it (as least the same standard of the plants, that most need it (as least the same standard of the plants). watering, or rather the next day, if the plants will R 2

eas

handsome or healthy) should be feverely cut, for a late blow, which generally proves a fine one in consequence. A judicious regular use of neat slender sticks is of much

advantage to geraniums, or other potted plants.

What has been faid of geraniums, applies to all those Exotics, called Greenhouse Plants, in the management of which, it is a material thing not to shift into too large pots, as the roots run directly to the outsides, and so would be too hastily brought to require the biggest pots. Another thing is, to take off some of the top soil, not only as directed in spring, but once or twice in the summer; and always before housing in autumn, and replacing it with a rich compost, as one of almost all rotten cow dung, which being black, is the most suitable to the eye, and it is cool and nourishing.

It is material to neatness, and the end of ornament, (for which plants are chiefly potted) that the pots should be occasionally washed, or scoured, and by no means suffered to get mouldy. This is a point so little attended to, that we sometimes see a beautiful plant in a very disgusting habitation. It is equally offensive, and injurious, to suffer the surface earth to get mostly, or caked hard by the necessary waterings; to prevent which, often stir it a little depth, and lay it smooth

which makes all look creditable.

Pinks are fometimes layered, or more usually propagated by cuttings, or pipings, about Midsummer; and may be also by slips, set in March, April, or May, with, or without roots, four inches asunder. Cuttings should be young strong shoots of three or four inches long, taken off just below a joint; from which stripping the lower leaves, and cutting the top ones short plant them in a fine good soil, about two inches asunder, and in depth full half of their length. They will strike root, so as to be fit to move, in seven or eight weeks, with a little earth about their roots; or may be left to an early time in the spring: but where the designed, they will be best six inches asunder. They may

late nce. nuch

the or au-

ng. nent, pots

ittle t in ive,

oth,

and Lay, ingliches rip-

ort funwil igh

nay thi

hey nay

may be either put in pots, or borders, where they are to blow, or rather into a nurfery-bed, to grow a year at fix inches distance. Pipings are obtained by drawing the heads of the young shoots out of their sockets, of the length of cuttings. In both methods, push the shoots carefully into the earth, gently prefs the mould about them, and give a watering; shade also from much fun. They will strike more certainly, and much sooner by being covered close with a hand-glass, as much as possible air-tight. They must be kept cool, by occafional watering; but when under glass, they will not need fo much watering or shading, or may do without any; for though the inclosed air is warmer, it is always more humid, which refreshes the cuttings with answerable supply for their support; and it is this moitture and warmth that facilitates the growth. When they appear to be growing, the glasses must be raised, and in a short time removed. To raise pinks from seed, follow the directions given for carnations.

Polyanthus is propagated by parting the roots in autumn, or (for new varieties) by feed fown and managed (nearly) as directed for auriculas: But as this flower is not fo delicate in the cultivation, it may be fown in borders, where there is only the morning fun, any time from August to April; and as soon as the plants are at all big enough to prick out, fet them four inches afunder; and fometime in August, plant at fix inches, where they are to remain for their first blows which should be attended to, in order to mark the best flowers, dividing these into two forts, prime and midling; and the rest may be either planted into ordinary ground in plantations, &c. or cast away: There will be but few real good ones in a great many; but the culture of this plant is so easy, that it is worth while to try for them. Some fow in pots, and boxes, in December, placing them in the fun, and houfing them in fevere weather; and when the plants appear, fet them in an east aspect, left much sun destroy the young plants;

feed may be covered a little less than a quarter of an inch. Both seeds and seedling plants should have occasional watering, as moisture suits them.

A composit for the polyanthus is simply a light loam, (as the first spit from the pasture rotted down with the turf) and about one fourth part cow dung or wood pile earth. If the loam is strong, a little drift sand amongst it will be proper. The polyanthus grows any where, but a cool soil and situation suits it best; and some composit, as the above, with an east border, is necessary

in order to a capital blow.

Tuberofe is blown finest in a hot-house; but if planted in pots, and plunged at the back of a hot-bed frame, it fucceeds very well. This will be best done about Mid-April, as fooner they are apt to get too tall before they can fafely be exposed abroad. Provide a good fresh light earth, and use no dung, except a little rich and dungy, to lay an inch below the bottom of the bulb; fill the pots only three parts, and place the root only half way, or a little more, in it. Let the mould be somewhat moift, but give no water till the shoot appears, and then moderately; at which time, fill up the pot, just to cover the bulb, which should be but barely hid, when the pot is full. The best shaped pots for bulbous roots is, when the bottoms are as wide as the top; and the fize for the tuberofe should be those of cight or nine inches diameter at top, according as the bottom is for width; for the more space below, the less is required above.

As the shoots advance in growth, the more air must be given; and as freely as possible on mild days, shutting close on cold nights, and almost so on moderate ones. When they get too high for the frames, and the season is forward, with kind weather, they may be plunged in the ground, close under a warm wall; and a covering of mat contrived to protect them a while on nights, or may do if left to take their chance. If

the weather is foul, they may be housed in a good window, for a week or a fortnight, and then put in the ground as directed above. Here let them remain, giving occasional watering, (and freely in dry weather) till in flower; when the house (allowing them light and sun) will be their proper residence, for their sine powerful scent, and to protect the blow, that it may the longer continue. In their flowering state, they will want much water.

The heat on which this flower is forwarded, should be moderate, otherwise it will run up too sast. If planted under a fouth wall in May, covering the root about an inch, and guarding against much wet till it is growing, it will do for a late blow: A hand-glass of course would be serviceable, both to affist it in shooting, and shelter it from unkind weather; but close covering is as much as possible to be avoided. Fresh roots are imported every year;—the double never flowers twice with us, but the single may, if kept in a dry warm room.

## A CALENDAR.

i

it

iı

Ł

I

1

E

1

F

B

F

0

P

A

V

I

B

E

THE general work of gardening has been pretty fully spoken of, in the parts concerning the formation, cultivation, and management of a garden, propagation, &c. The particular culture of esculents, herbs, fruits, and slowers, has been treated in the sections appropriated to each. It therefore remains to give here little more than short hints, by way of assisting recollection, and to make proper references to the pages, where farther instructions may be found of those that need, or chuse to consult them.

What is faid concerning feeds and fowing, page 57 to 64, must be attended to. It need only be farther observed, that as to the feason proper to do the several works of gardening, it is not the same (exactly) every where, as foil and situation make a difference.—The time mentioned in this calendar is, that which the author judges will be found most generally right in the midland counties, as the extremes of north and south

make a great difference in this bufinefs.

The work of gardening being very multifarious, it would be a practice not unworthy, even the skilful gardener, to make it a rule, once a week, to consider what is to be done the following week; and to make memorandums accordingly, numbering them in the order he would have them performed.—Thus he would never be at a loss, what to set himself, or his labourers about, and the mortification of omissions, or appearance

,

-

e

,

ance of neglect, would be avoided: This calendar, it is prefumed, will be found a ready and sufficient affistant upon such an occasion, the author having endeavoured to make it plain, comprehensive, and as concide as possible.

# JANUARY.

LET every thing be done now, that the weather and circumstances will permit, (if not absolutely necessary) in order to lessen the work of next month, which when it happens to be an open season, is a very important one in the way of gardening, in which the loss of a single fine day is of consequence.

## MISCELLANEOUS WORK.

Frost protect things from, as they need it. Earth-up roots bared or disturbed by frost. Dung for hot-beds .nould be duly attended to, 171. Manure and compost heaps turn frequently over. Espaliers, garden frames, and such things, rectify. Tools, make, repair, sharpen and brighten, 276. Fruit, onions, &c. the stores of, look over, 263, 229. Brush-wood, prepare ready for sticking peas, &c. 231. Planting, trench and prepare ground for, 28, 95, &c. New-planted trees, protect and tie to stakes, 89, 100. Old trees dig about, and drefs with some manure, 45. Prune espalier trees, standards and shrubs, 160, 166. Mofs, clear trees and shrubs from, in moist weather. Vermin fet traps for, kill bull-finches, &c. Webs and nefts of caterpillars, flugs, fnails, destroy. Beds and borders, weed, stir the ground, and rake. Cauliflowers and lettuces in frames, &c. attend, 214, 227. Endive, tie up, when dry, to blanch; and protect it, 220. Cions

i

ł

0

E

6

7

6

C

F

S

C

E

Si

11

E

Cions, procure for graffing, except apples, 82, 85.

Hot-beds, prepare for, or make, cucumbers, &c. 169, 177.

Drain ground, fcour ditches, plash hedges, &c.

#### SOW

Cucumbers, 176. Melons, 192. Peas 230. Beans, 206. Spinach, 243. Radifhes, 238. Lettuces, 226. Creft, 249. Mustard, 253. Carrots, 212. The five last on beat; to which may be added, rape and laplettuce, 228, as fallading; towards the end of the month, however, they may be sown on warm borders, the sallading being under close hand-glasses.

#### PLANT

Mint on heat, 253. Cabbages at distances as 211. Trees and shrubs of the deciduous kinds, grape vines, currants, geoseberries, and raspherries, if mild weather, so that the ground will work loose. Layers may be removed; but rather prepare the ground now for planting them next month, 95, &c.

#### PROPAGATE

Trees and shrubs by fuckers, layers, cuttings, 64, &c.

#### FLOWERS.

Pots of, fee December, tulips, anemonies, ranunculuses, hyacinths, narcissus, &c. above ground protect, 289. Bulbous and tuberous roots now plant for a late blow, or in the next month; but preserve them if choice forts from much wet, lest they rot, 286.

Auriculas, if disturbed by frost, dress and protect, 358. Carnations, and all hardy plants, in pots, protect, but give them as much air and sun as may be, 361.

Flowering shrubs may be planted, if open weather, covering the roots well; but it is better done next month, getting the ground ready now, 107, &c.

NURSERY.

ſŧ

e

.

,

,

e

r

5,

,

e

t

# NURSERY.

Vermin, guard against in time, on seed beds, &c. 72.

Dig beds for fowing, next month tree seeds, &c. 71.

Protect seedling trees (particular exotics) from frost.

Plant, or transplant, hardy things, cover the roots.

Prepare ground for next month's planting out seedlings, or stocks for graffing another year, 72.

# FEBRUARY.

WHEN the ground can be conveniently worked, this is a very bufy month, and no time must be lost, nor hands spared, that every thing may be done in its proper, or earliest season.

The last week is the principal, in which many things are to be done, and some full crops sown: The skilful gardener is properly aware of this, but ordinarily the month of February is too much neglected.

### MISCELLANEOUS WORK.

Ground, prepare for planting and sowing, &c. 45.

Borders should be stirred, dug, or dressed, 29, 138.

Gravel walks, weed, moss, put in order, and roll sirm, 54.

Turf, prepare the ground for laying, by levelling.

Grass plats and walks, crean up, cut the edges, 54.

Composts and manures, turn over, and break well.

Hot-beds, attend regularly, and no neglect, 179, &c.

Stable dung, for hot-beds, now manage properly, 171.

Caulissowers and lettuces, see to, as in the last month.

Earth-up and protest plants from frost and wind, 49.

Stick-peas, neatly, when about five inches high, 231.

Weed and thin crops, as winter onions, radishes, &c. 49.

Endive, attend, to blanch and ridge when quite dry, 220.

R. 6

Vermin and insects, see to, as mice, snails, slugs, &c. 233. Birds, chiefly bull-finches, do much mischief now. Prune wall and other trees, but first grape vines, 129. Moss and canker clean trees of, most weather. Cions for graffing provide, 82, and use them, 83, &c. Edgings of thrist, a good time to make or repair, 55.

#### sow

Cucumbers, 178, 219. Melons, 192, 228. Peas, small, 231, large, 232. Beans, the broad forts, or the mazagans, if wanted early, 206. Radishes on heat, or not, 239. Lettuces on heat, or not, 227. Small fallading on heat, or on a warm border under glass, 249. Cabbages, the sugar loaf forts, 211; or if early ones are wanted, sow the Yorkshire sort on heat, 212. Savoys, 241. Onions, 228. Leeks, 225., Parsley, 254. Spinach, 243. Carrots on heat, or not, 212. Parsneps, 230. Celery, 216. Kidney-beans on heat, 224. Turneps on heat, 244. Cauli-stewers on heat, 214.

#### PLANT

Cucumbers, 179, 184. Melons, 195. Cauliflowers, 215. Cabbages, 211. Horfe-radifb, 221. Garlick, 221. Recombole, 255. Shalots, 243. Cives, 248. Mint on heat, 253. Potatoes, early forts, on heat, and warm borders, 235. Vines, wall, espalier, and standard fruit trees, forest trees, and deciduous shrubs, 30, 95, 107, 112.

#### PROPAGATE

Trees and shrubs by graffing, 83, by suckers, layers, and cuttings, 64. Sow kernels, stones, and seeds of fruit, &c. on fine well broke earth, providing exerces a little heat, 71.

FLOWERS,

3.

c.

e

r

1

r

## FLOWERS.

See last month. Biennials and perennials plant, 283.

Shrubs protect, &c. 119: prune and dig about, 111.

Carnations, &c. housed, bring abroad mild days.

Auriculas, pots dress and regularly water, 358.

Auricula and polyanthus seed should be sown-now, 359.

Bulbs and tubers, plant soon and pot some, 286.

Water pots, particularly woody and hardy plants.

Annuals, sow about last week, 281; some in pots, 282.

### NURSERY.

See last month. Sow hardy trees and shrubs, 71. Transplant hardy seedlings of last year, and stocks for graffing next year, or the following, 72.

# MARCH.

THE first week in this, like the last in February, is very valuable to the good gardener, and must be made the best use of by those who would have things tolerably in season, and well surnished for the summer. It is therefore proper to have no regard to the charge of necessary affistance. Nature now waits for us, let us not neglect to attend upon her: This is the universal seed-time. See management, page 56.

# MISCELLANEOUS WORK.

Order and neatness are now principal objects, 54.
Vacant ground, dig and apply manure where wanted.
Borders dress, by weeding, digging, &c. see last month.
Gravel walks, clean, roll, re-lay, or make new, 54.
Edgings of thrist and box, if mild, repair, or make, 55.
Grass

Grafs plats and walks make, cleanse, mow, cut edges, 54. Herb-beds weed and drefs, fee article balm, 246. Weeding in general should be begun in time, 49. Asparagus beds, weed, carefully fork, and drefs, 202. Ditto, in dry weather, water as recommended, 205. Strawberry beds, weed, stir the mould, and dress, 165. Artichokes, dress, &c. towards the end of the month, 202. Composts heaps, turn, screen, or sifr, for pots, &c. Vermin, infects, and destructive birds, see to, 233. Earth-up peas, beans, and whatever else needs it, 49. Stick peas in time, and stop them, or not, 231, 233. Stakes to trees, &c. fee that they are fast, 100. Graff now, but apples towards end of the month, 81. Prune wall trees without delay, but first vines, 148. Bloffoms of choice wall-tree fruit, defend, 145. Prune, dig, dress, thrubberies and plantations, 108. Hot-beds carefully attend, 180, and make new ones, 183. Dung for future hot-beds, manage in worked heaps, 170. Cauliflowers, &c. under glass, give air freely to, 214. Stir mould about ditto, and also lettuces, 215, 227. Prick out cauliflowers, cabbages, lettuces, &c. Orchards, dung, drefs, prune, or smoak them, 43.

## SOW.

See last month, cauliflowers, favoys, onions, &c. Radifbes, the spindle rooted, 239. Lettuces of sorts, 226. Small fallads, 249. In the first week:—Alexanders, 201. Asparagus, 203. Beets, 208. Hamburgh parsley, 230. Salfafy. 240. Scorzonera, 241. Skirrets, 243. Finochio, 250. Red cabbage, 212. Turnep radifbes, 239. Second week: Turneps on heat, and in open ground, 245; and kidney-bean on heat, or a warm border, 223. Last week: Brocoli of the early purple autumn sort, 210. Nasturtiums, 253. Capsicums, 248. Love apples, 259. Herbs of all sorts, 246, &c. Strawberries, particularly alpines, 77.

### PLANT

Trees and shrubs, 30, 95, 107, 112. Herbs in rooted flips or cuttings, 246, &c. Strawberries, 38. Asparagus, 204. Artichokes, 201. Potatoes and Jerusalem artichokes, 222. Lettuces, 226. Caulistowers, 214. Other things as last month.

## PROPAGATE

Trees and shrubs, by graffing, 83; by suckers, offsets, layers, and cuttings, 64. Herbaceous plants, by parting roots, &c. 285.

#### FLOWERS.

The hardy kinds of flowers in pots that have been housed, should be inured by degrees to the weather, and soon left out on nights: None should remain under cover more than necessary.

Pot desirable hardy plants for moveable ornaments, when in flower; but not too many, 278, 282.

Auriculas, if not before, dress, and regularly water, 358.

Carnations dress as directed for auriculas, 258.

Carnations drefs as directed for auriculas, 358.

Tulips, hyacinths, &c. of the best sorts, protect, 289. Water potted plants duly as the weather is, 277. Sow annuals, 273. Biennials, 282. Perennials, 283.

Take up, remove offsets, and divide fibrous rooted perennial flowers about middle of the month, 285.

Layers of carnations, pinks, &c. take up carefully foon, and pot or plant with earth to the roots, 360.

Seedlings of ditto, and other things, plant out.

Anemonies, ranunculuses, and bulbs, may be put in (east border) the first week, to blow late, 286, 287, &c.

Box, thrift, daisies, pinks, &c. plant soon for edgings.

S

S

## NURSERY.

Remove litter, weed, stir the ground, and rake neatly. Prune into form, shorten the leader, &c. to make a head, &c. 69.

Graffs of last year cut to a few eyes; behead as at 94.
Transplant and sow as last month, and do it quickly.
Exotics, or tender plants, sow on a gentle hot bed, 71.
Water give in a dry time to seeds, seedlings, cuttings, and newly planted things; but not over much, 52.

# APRIL.

Is by any means the proper early spring cropping of the ground has been prevented, make no delay to finish, and to get the garden into a complete state of cultivation. This month may be mild enough to invite us abroad, to traverse the walks, and view nature in her spring attire, all blooming and benevolent. Let nothing therefore be met with that appears stovenly, or disgusting. See page 54.

#### MISCELLANEOUS WORK.

Borders, &c. weed, stir, rake, and clean up neatly, 49. Quarters also weed, particularly beds of onions. Gravel walks and grass plats, put in order, roll, &c. 54. Turf, get, lay, but water frequently if dry weather. Edgings of box, &c. make, repair, trim, or cut low, 55. Watering omit not where necessary in a dry time, 50. Pruning finish all soon; head down young trees, 130. Graffs, see to, that the claying remains safe on, 84. Blossoms of wall fruits, protect in bad weather, 145. Dung for hot-beds, collect and take care of, 171. Hot-beds, make in due time for fruiting cucumbers, 183. Hot-beds,

Hot-beds, for melons, tender annuals, &c. 194, 273, 279. Asparagus, strawberries, artichokes, see last month. Caulistowers, stir mould about, and earth up, 214. Peas, earth up, and stick before they droop, 231. Beans in blossom, crop the tops and earth up firmly, 207. Weed and thin all seedling crops, by hand or hoe, 49. Prick out celery and plants of every kind as sit, 50. Potatoes, early fort, earth up, protect from frost, 235. Lettuces, tie up close, and stir the ground about, 227. Cabbages, earth up, and also tie up forward ones, 211. Caterpillars, snails and slugs, search often after.

#### SOW

As foon as possible, what was omitted last month, or the preceding. Then, Salfafy, 240. Scorzonera, 241. Pumpions and gourds, 237. Late Savoys, 241; and Cauliflowers, 215. Boorcole, 209. Brocoli, 210. Bruffels sprouts, 210. Chou Milan, 218. Chardons, 218. Kidney beans, 223. Cabbages, chiefly the large sugar-loaf for coleworts, 211, 219. Herbs, culinary and medicinal, 246, &c. Nasturtiums cold ground, 253. Basil on heat, 247.

Succession crops, of cucumbers and melons, for handglasses, &c. 188, 198, 200. Peas, large and small, Beans, the broad forts. Savoys, carrots, turneps, celery, lettuces, finochio, spinach, and radishes cool ground, small sallading, weekly, on a south border,

onions to draw young, 61.

## PLANT

Strawberries yet, but alpines succeed best so late, 38.

Asparagus, 204. Artichokes, 201. Lettuces, 226.

Chives, garlick, rocombole and shalots, first week, see

February. Cabbages, early and late, 211. Cauli
flowers, 215. Kidney beans that have been raised on
heat, 224. Potatres for a full crop, 234. Herbs in
rooted

r

n

to

t

f

2

rooted flips, 246, &c. Trees and shrubs immediately, and do it in the best manner, water, cover the roots, and stake the stems, 97, 107.

# PROPAGATE

Trees and shrubs, by graffing, layers, cuttings, and fowing, which may yet be performed, 64, 71, 79. Herbs, by slips, or cuttings, in a good soil, and a shady situation, but not under trees, 246, &c.

# FLOWERS.

Sow, in the first week, (if not done before) annuals, 273, 279, 280. Biennials, 282. Perennials, 283.

Plant, or prick out, annuals as the forts require, 274.

Biennials and perennials of late blowers, may yet be transplanted into borders or pots, giving an immediate watering, and shading a few days from sun, 283.

Carnation layers, taking them up carefully with a scoop trowel, 276. Pinks, the same. Tuberose, 357.

Tulios, ranunculuses, anemonies, &c., of choice forts.

Tulips, ranunculuses, anemonies, &c. of choice forts, protect in severe cutting winds, 288.

Auriculas in bloom, shelter from rain, wind, sun, and support the stems by neat forked sticks, 359.

Pots of flowers, shift, and dress, tie up, water, &c. 363.

Crocus leaves tie up, do not cut them off.

## NURSERY.

Weed, water, stir the soil, rake neatly, and clean up, 69. Transplant (yet) seedlings of trees and shrubs; the evergreen sorts it is now a good time for, 72.

Sow (if not done before) the feeds of forest trees, flowering shrubs and evergreens: but keep them cool, by watering, as every thing should be, that is sown or transplanted late in the spring: Yet they must not be kept soaked with wet, 71.

s,

d

# MAY.

LET this charming month be ushered in with due respect, by the gardens being in excellent order, to which end let no help be spared, when the gardener is not competent to perform the work himself: It is often too much for the most industrious man.

We now gather vegetables that have stood the winter, and been the care of many months, with some of the products of spring also; and it is the hope and fruition of reward that sweetens labour: All the senses are gratified at this season.

— The foftening air is balm; And every fense and every heart is joy!

THOMSON.

#### MISCELLANEOUS WORK.

Neatness must be pursued, stir the ground, rake, &c. 49. Gravel walks and grass plats, keep in good order, 54. Weeds, destroy every where, by the hand or hoe, 49, 54. Water, if dry weather, new planted trees, shrubs and slowers, strawberries, caulislowers, &c. 40, 51.

Thin all forts of feedling crops enough, and in time, 49. Prick out lettuces, celery, brocoli, boorcole, cauliflowers,

favoys, cabbages, leeks, &c. 50.

Earth up potatoes, peas, beans, cabbages, celery, &c. 49.

Tie up forward lettuces, and early cabbages, 211, 227.

Cucumber plants, give air, water, shade, train, 185, &c.

Hot-beds, make for cucumbers and melons, 173, 189, 199.

Regulate wall-trees, vines, and prune figs, 132, 149, 151.

Graffs attend to, and repair the claying, &c. 84.

Thin fruit that is superabundant on wall-trees, 146.

Beans, top, when in blossom, and earth them up, 207.

## sow

Nasturtiums, herbs, and tall kidney beans, first week, 253, Endive, 220, and purstane, 255, second week, Cauliflowers about the middle, 215. Celery, 222. Pumpions and gourds, 237.

Succession crops of cucumbers for picklers, 190. Melons for mangoes, 200. Dwarf kidney beans, celery, radishes, turneps, cabbages, savoys, brocoli, peas, beans, finochio, salfafy, scorzonera, chardons, spinach, lettuces, radishes, and small sallading, chiefly first week.

## PLANT

Kidney beans that have been forwarded on heat, 223. Cucumber and melons, second crop, 188, 198. Forward gourds, 237. Lettuces, 226. Caulissowers, savoys, cabbages, coleworts, 217, 219. Celery, if forward, in trenches, 217. Artichokes, 201. Potatoes 234. Nasturtiums, 253. Capsicums, 248. Loveapples, 259, and basil, 247, towards the end of the month. Herbs, by parted roots, 246, &c. Trees and shrubs may yet succeed under good management, 101.

# PROPAGATE

Herbs, culinary and medicinal, by flips and cuttings, but rather the latter. For fage it is now the best time, 246, &c. See Flowers, article slips, &c.

## FLOWERS.

Sow annuals of all forts for a late blow. Scarlet bean, fow as a flower to run up pales, &c. 273, &c.

Thin feedlings foon, that they may not be weak, 273.

Prick out, or plant, the tender annuals in new hot-beds, pots, &c. as directed, 274, 276, 278.

Hot-beds of flowers, manage, as to air, water, &c. 286.

Biennials

?s

3

Biennials and perennials, thin in time, and water them; also prick out any that are forward enough; they may yet be sown, 282, 283.

Auriculas out of flower, remove out of the sun, 359. Tuberoses, pot on heat, or under a south wall, 357. Tulips, anemonies, &c. in beds and in flower, protect, 288.

Bulbs and tubers of dying spring flowers, take up, 285.

Slips and cuttings of pinks, double wall-flowers, double fweet williams, double fcarlet lynchnis, double rockets, and lychnidea, plant as soon as the young shoots are forward enough, 364, 333, 343, 346, 344.

Geraniums, plant cuttings of last year's shoots, 361.

Water seed-beds lightly and moderately in a dry time,
280; and pots of flowers regularly, 277.

Air, give to housed plants freely, as the season is.

Dress, shift, and tie up, flowers and shrubs in pots, 363.

Pot some ten week stocks, mignonette, &c. 276, 278.

Support spindling carnations, &c. and weak shrubs, 55.

Stir the surface mould of pots of flowers, 362.

#### NURSERY.

Weed, water, occasionally shade tender seedlings, 69. Seed-beds, keep cool, for without moisture, germination cannot be expected; but give water lightly, so as not to cake the ground, 51.

# JUNE.

In this month the gardener begins to find some pause to his labour. The ground is now fully cropped, as to principals, and the chief business is to see that the various plants, according to their different ages of growth, do not stand in need of the necessary assistance of culture, or good management. Particularly attend to trained trees, &c. to regulate them before they get into disorder:—This do once a week.

SI

## MISCELLANEOUS WORK.

Weed diligently, particularly close crops, 49. Stir the ground between open crops, and rake, 49. Gravel walks, grass plats, and edgings, see to, 55. Water, let it be duly applied where necessary, 51. Thin by hoe, or hand, all forts of crops fully, 49. Prick out things, celery, endive, favoys, brocoli, &c. 50. Cauliflowers shewing head, break leaves over, 216. Earth up high peas, beans, &c. fee the last month. Tie up the leaves of garlick and rocombole, 221. Blanch lettuce, white beet, and finochio, 208, 227, 250. Stick peas, and top beans when in full flower, 231. Cucumbers, attend duly, to air, water, train, &c. 185. Melons, ditto, prune, lay tile under the fruit, 195, &c. Prune wall-trees, vines and espaliers, 129, 149, 160. Blighted trees, pull off curled leaves, in time, and water them frequently with an engine, 52. Graffs that have clearly taken, unclay and unbind, 84. Bud, or inoculate, at Midsummer, or soon after, 89. Asparagus, finish cutting before Midsummer, 206. Herbs for drying, gather as directed, page 246. Seeds also attend to, and gather if any ripe, 59.

#### sow

Gucumbers, last crop, for picklers may do in coldground, if a good soil and sunny situation, 190. Pumpions and gourds may succeed as ditto, 237. Turnep radishes of all sorts, but chiefly the large white and black Spanish for autumn use, in cool ground, 239. Endive for a principal crop, 220.

Succession crops of celery, brocoli, peas, broad beans, kidney beans, radishes, lettuces, small sallading, purstane, turneps, cabbages, carrots, finochio, and spinach.

#### PLANT,

Cucumbers, 189. Melons. 199. Pumpions and gourds, 237. Nasturtiums, 253. Capsicums, 248. Love-apples,

XX,

0.

50.

85.

ind

34.

ld -

7.

ge

ol

ty

s,

c.

apples, 259. Leeks, 225. Celery, 216. Cauliflowers, brocoli, boorcole, savoys, cabbages, and such like greens, at two and a half feet, or rather more for cauliflowers; less for brocoli, and cabbages if a small fort. Seedling herbs, 246, &c. Moist weather at this season is very advantageous for pricking out, or planting, and it must not be neglected when it occurs: Water at the time of planting, and afterwards as the weather may require.

## PROPAGATE

Herbs by flips, or cuttings, in a good foil, and as cool a fituation as may be, not under trees, 246, &c.

Layer the young shoots of roses, evergreens, or any shrub, or tree, that does not readily strike root from older wood, or send forth suckers; but make the soil rich first with compost, or short dung, and water the layers frequently, 66.

Cuttings, or the young shoots of some woody plants,

may be made to ffrike root, fee page 312.

About the second week is the best time to plant cuttings of myrtles, which should be young wood and short, about two inches. Keep them cool.

#### FLOWERS.

Annuals, tender forts, pot and plant out into the borders; they will require a good foil, water, and a little shade at first, and chuse rainy or cloudy weather for the work, 276.

Pots of flowers fet where they have only the morning fun, but not under trees, or any roof, except for

ornament a while, when in blow, 278.

Trim, from dead parts, &c. perennials and biennials, 56. Carnations, and other spindling flowers, support, 55. Geraniums, plant cuttings of last year's shoots, 361.

Water pots of flowers duly, borders occasionally, 277.

R

Sp

0

Prick out seedlings of biennial and perennial flowers, particularly carnations, 360. Pinks, 364. Auriculas, 359, and polyanthuses, 365, into shady places.

Plant slips, &c. of wall-flowers, &c. see last month.

Layer carnations, pinks, and sweet williams, 359.

Auriculas should be set in shade, except for seed, 359.

Spring bulbs, the leaves being decayed, take up, 285.

Autumnal bulbs, plant at the end of the month, 286.

#### NURSERY.

Weed, water, stir the soil, rake it, and clean up, 69. Shade the tender seedlings, and late planted things, 51. Seed beds, spring sown, keep moist, and earthed up; in very hot weather, an awning of mats is advantageous on days. Seedlings in pots or boxes move into shade, but not under trees.

Thin young plants from growing thick and weak, 49.

# JULY.

Though in this month there is a ceffation from the great buftle, and more laborious works of gardening, yet "its many cares" still find employment for the willing hand; and most affuredly a good success in the end will not be attained without perseverance in the means. Let nothing therefore be omitted, that may tend to crown the gardener's credit with a continued production of fine vegetables, fruits, and flowers. The garden now abundantly gratifies the fight, the taste, the smell; and those who have the opportunity to enjoy it, should be grateful to Gob—and the gardener.

#### MISCELLANEOUS WORK.

Prepare vacant ground for cropping, and let as little of it as possible lay rude and unproductive.

Weed

s,

;

to

r.

le

do

Weed, fir the borders, hoe between crops, &cc. 54. Water cauliflowers, and whatever else may need it, 51. Gravel walks, grafs plats, and edgings, keep in order, 54. Box, yew, &c. should be clipped after, or in rain. Earth peas, broad and kid. beans, celery, cabbages, &c. Blanch white-beet, lettuce, and finochio, 208, 227, 250. Stick peas, and running kidney beans in time, 231, 225. Thin all small crops to their due distances, 49. Prick out celery, endive, brocoli, cabbages, &c. 50. Seeds, gather as they ripen, left the best are lost, 59. Herbs for drying, gather as foon as in flower, 246. Take up garlick, rocambole, shalots, 221, 225, 243. Cucumbers and melons, attend, water, train, &c. 185, 195. Pumpions and gourds, train, and water plentifully, 237. Artichokes, take off small side heads in time, 202. Wall-trees, &c. regulate, and occasionally prune, 132. Vines stop, and take off the little side shoots, 150. Thin wall trees, &c. of superabundant fruit, 146, 156. Bud-graff, or inoculate, fruit trees, roles, &c. 89. Blighted wall-trees, attend to, fee the last month. Strawberry Runners take off; except the first, 77. Kidney Beans, runners, train, and water if dry, 225. Ants, flies, and wasps, take by vials of sugar water.

#### SOW

Brocoli, first week, cool ground a little, for late use, 210. Endive, principal winter crop, in open ground, 220. Peas and beans, early sorts, may yet sow, 208, 232. Kidney beans, dwarfs, first week, south border, 224. Carrots, a few, cool ground, first week, and water both seeds and roots if dry weather, 212.

Radishes of any kind, but chiefly the large black and white Spanish turnep forts, water, 240.

Lettuces, the hardier, or winter forts, open ground, 226. Spinach, first week, the round in cool ground, and in the last week the prickly seeded, 243.

Onions, a few Welch, and Strasburgh, second week, 228.

V

Coleworts, first week for winter, last week spring, 219. Turneps, any sort, both early and late in the month, 244.

#### PLANT

Celery at six inches; Leeks the same or more. Endive, lettuces, coleworts, at a foot. Cabbages, savoys, brocoli, boorcole, and cauliflowers, at two feet, or a little more in a rich soil, particularly the latter: Give water at planting, and two or three times after, if not much rain should fall.

### PROPAGATE

Herbs, lavender, rosemary, sage, propagate yet, by cuttings, or slips, occasionally watering, 246, &c.

Trees and shrubs, by laying shoots of the present year; i. e. of those that are not apt to strike from older wood. Slips and cuttings of some sorts, may strike, by the help of a band-glass, 66, 312.

#### FLOWERS.

Stir the flower borders, and rake them neatly, 54. Pots of flowers, fet in shade, and regularly water, 278. Carnations and double fweet-williams, layer, 359, 333. Pinks, plant flips, cuttings, pipings, or layer, 364. Geraniums, double lychnis, lychnideas, double wall-flowers, Rockets, plant cuttings, or flips, 344, 333, 361, 346. Succulent plants (as aloes) may now be let abread. Annuals, plant out tender forts into borders, 286. Ditto, quick blowers may still be fown, 334. Biennials, thin feed beds of, prick out, water, &c. 283. Perennials, ditto, particularly auriculas, 359. Carnations, 361. Pinks, 364, and polyanthus, 365. Larkspurs, thin and pull up all the fingle ones, 335. Stocks, pull up most of the fingle ones, 332. Seeds, gather very regularly as they ripen, 56, 58. Bulbous and tuberous roots take up in due time, 285.

Bulbs of autumn, as faffron crocus, plant now, 292.

Trim plants and shrubs, straggling branches, &c. 56.

Support weak flowers and shrubs by proper ties, 55.

Minionette, sow in pots to flower in winter.

### NURSERY.

Weed, water, shade, young tender seedlings, &c. 69.

Prune away suckers, or shoots from stems, &c. particularly those that have been grassed, 93, 94.

Thin seedlings, shade by a mat, &c. new planted ones, but not from night dews, water, &c. 73, 51.

# AUGUST.

In this month (as in some measure before) the gardener anticipates products of the future year, and sows various vegetables in autumn to stand the winter, for spring and summer use; so that, in this, and other respects, August is in truth an important season, as will be seen by the work directed to be done. The times for the several sowings should be pretty exactly observed in order to success.

# MISCELLANEOUS WORK.

Weed, water, stir borders, rake and clean up, 50, 54.
Walks and grass plats, attend, roll, mow, sweep, 54.
Thin by hoe, or hand, young crops, in dry weather, 49.
Water ditto, as also new sown beds, regularly.
Prick out celery, and other things as winter greens, 50.
Earth up peas, beans, kidney beans, celery, greens, &c. 49.
Blanch endive, beet, chardon, finochio, 220, 208, 218.
Dig, or use a strong hoe, between rows of plants, 49.
Vacant ground, clean, and prepare for use, 46, 47.

2 Stick

Stick peat, and take up the haulm of old crops, 231. Stake tall plants which are standing for feed, 59. Seed plants support, and gather seed as it ripens, 59. Herbs, gather for drying just when in flower, 246. Onions, press down the leaves to the ground, 229. Shalots, garlick, rocombole, take up, 249, 227, 261. Grape vines, prune, nail, and keep in due order, 150. Wall-trees, espaliers, climbing fhrubs, &c. regulate, 133. Infects about wall-trees, attend to. See blight, June. Wasps, &c. take in trees, by vials of sugar water. Budding may yet be performed, first week, 89. Buds that have taken of former work, unbind, 93. Net fruit trees up, to keep off birds, and also fingers. Gather fruit before the fun has shone long upon it. Mat up currants and geofeberries for late fruit, 164. Strawberries, clear from runners, weeds, leaves, 165. Cucumbers, pumpions, and gourds, train, water, &c. Pickling cucumbers should be gathered twice a week. Melons, prune, train, water sparingly, 195.

#### SOW

Coleworts in the first week, 219; cabbages in the fecond, 211; cauliflowers in the third, 214. Onions, Welch, a full crop, and a few Strasburgh a warm border, first week, 228. Lettuces, at the beginning, middle, and end of the month, 226. Small fallading, in a shady place, and water it, 249. Chervel and American cress, second week, 248, 250. Radish, both spindle and round rooted, 245. Kidney beans, dwarf, on a warm border, first week, 225. Spinach, round first week, prickly third week; the former at broad cast, and the latter rather in drills, 243. Turneps, first or second week, 244. Carrots, ditto, 214. Herbs first week, 246, &c.

#### PLANT

Without delay, leeks, celery, lettuces, endive, cabbages, coleworts, late brocoli, and boorcole, distance as last month

XX.

th

month, though every thing planted late, may be so much the nigher, generally speaking one third. Strawberries and berbs, culinary and medicinal, towards the end of the month, that they may be well rooted before winter, 39, 246, &c.

### PROPAGATE

Trees and shrubs, by laying young shoots in fine rich earth, and keep the ground cool about them, 69.

#### FLOWERS.

Decayed parts, take off, trim, and tie to flicks, 56, 57. Shrubs, ditto, thin a little, and prune off fuckers, 111. Edgings, or hedges of box, yew, &c. may be cut now. Water potted flowers regularly, also others, 277. Ditto all new planted things, and shade them, 275. Annuals, hardy, fow towards end of the month, 287. Minionette, plant in pots, to flower in winter. Biennials and perennials, plant, last week, 289, 291. Saxifrage pyramidal, and double plant in pots, 355. Geraniums, raised from cuttings, (or seed) pot soon. Ditto, pots of, &c. stir, or fresh earth, 364. Auriculas and polyanthus, transplant, part, &c. 359, 365. Carnations yet layer; transplant early layers, 359. Pinks from early cuttings may be fit to move, 364. Sweet Williams layer, or transplant if rooted, 333. Bulbous roots, as lilies, &c. take up for planting, 285. Bulbous offsets, replant them without delay, 286. Bulbs of autumn flowers, plant in first week; see atamasco, Guernsey, &c. Lillies, 362. Succulent plants, shift (best season) first week, 364.

#### NURSERY.

Prune suckers, side stem shoots, straggling and luxuriant ones from the head; stir the ground, weed, water, thin seedlings, plant, shade, &c. 69, 51.

SEP-

Library Syriaurodia +

# SEPTEMBER.

GARDENS begin now to fail of their wonted beauty, and therefore dying flowers, all litter, and every thing unfightly, admonish the gardener to trim his plants, and clean the ground frequently, that all may be pretty if not gay. An attention of this fort, stirring the ground, and raking it, will give an air of freshness and culture highly pleasing and creditable.

#### MISCELLANEOUS WORK.

See beginning of last month, twelve first articles. Shrubs free from fuckers, dig about, &c. '111. Prepare ground for planting trees and shrubs, 103. Turf, lay as a good time, beat, roll, and water. Gather fruits as they ripen, and store them well, 262. Grapes, tie fine ripe bunches up in gauze or crape. Figs, keep in close training to ripen the fruit, 151. Cueumbers cover on nights to prevent the spot. Pickling cucumbers, gather before they get spotted. Melons carefully protect from cold and wet, 200. Cauliflowers, prick out, put some on slight heat, 214. Ditto, Michaelmas crop, if dry weather, water often. Lettuces, prick out, at 4 or 5 inches, fouth border. Herb-beds should be cleared and dressed this month, 246. Nasturtiums gather before ripe for pickling, 253. Onions, being dry and hard, take in, fort, &c. 253. Garlick, Shalots, and rocambole, tie up, and store, 221. Seeds, fuch as are well dried, drefs and put up, 56, 59. Beans, late, top them as foon as in flower, 207.

### sow

Spinach, turneps, Welch onions (thick) and endive, first week, for late spring use. Radishes of all forts, but chiefly

ted

XX.

and im all rt,

of

chiefly the large black turnep, 240. Small fallading, every ten days, warm borders, or under glass, 250. Corn fallad, 250. Chervil, 248, and forrel, 257.

#### PLANT

At distances as before, coleworts, endive, cabbages, saveys, brocoli, boorcole, Brussels, sprouts, chou-milan, and celery; also lettuces on dry warm ground, 226. Herbs, pot and medicinal, from parted roots, or offets, 246, &c. Shalots, garlick, rocambole, 249, 227, 261. Strawberries, any time this month, (the sooner the better) dress old beds and plants, 38, 77, 165. Shrubs, begin to plant towards the end, but let not the roots be long out of ground, 106. Cunrants, gooseberries, and ruspherries, may be planted last week, 31, 38.

### PROPAGATE

Trees and shrubs, by laying young shoots, and at the end of the month, cuttings may be planted, as of goofeberries, currants, laurels, honeysuckles, &c. 66.

#### FLOWERS.

Remove dead ones, trim the decaying, tie up, &c. 55, 56.

Annuals, fow fome of the hardy forts, first week, 281.

Biennials, plant out, reserving a few for spring, 283.

Perennials, ditto, also take up, and part old roots, 283.

Pinks, from cuttings, &c. (if well rooted) plant out; also carnations, sweet-williams, &c. from layers, 360.

Geraniums, from cuttings, or feed, plant without delay, in small pots, shortening the roots, &c. 362.

Auriculas, dress, shift, slip, place in shade, 359.

Polyanthus, plant, part roots, or sow the feed, 365.

Bulbs of autumn flowers, plant yet in first week, see last month; and those of spring in last week, as crocuses, early sulips, common anemonies, &c. 286.

S 4

Lilies

31

of

al

I

(

Lilies and other scaly bulbous roots, plant soon, 287. Offsets from bulbs must be planted immediately, 287. Beds for bulbous and tuberous roots, prepare, 293. Edgings of box, thrist, or pinks, plant, cut, or repair.

Pots of flowers bring from shady situations to more sunny ones; exotics, put in time under some degree of shelter, according to their nature; the succulent plants are impatient of wet, and cold, as also variegated geraniums; take them in soon; but give plenty of mild air.

Minionette in pots for winter, place under a fouth wall.

## NURSERY.

Weed, fir the foil, clean up, and water, if dry weather. Dig about young trees, at the end of this, or the beginning of next month, as directed, 79.

Prepare ground for planting, next month. Stocks and feedlings, and fowing feeds of trees and shrubs, 71, &c. Cherry Stones may now be sown. Evergreen seedlings should be planted out, last week, and watered, if a dry time, 72.

# OCTOBER.

This is the chief month of the year for planting trees, shrubs, &c. No part of it should be lost, in either working the ground well for the purpose, or putting in the plants without delay: Early planting, if the ground is fit, is of much consequence. Esculents are to have their winter quarters provided them as soon as possible in the month, as at the end of it the weather is often bad.

Now the virtues of industry and perseverance will be tried to keep the grounds clean from falling leaves, &c. The garden, however, ought yet to be a source

SECT. AA.

)e-

nd

d-

d,

of pleasure, and the weather is often still inviting abroad: Surmount impediments.

# MISCELLANEOUS WORK.

Dig, dung, trench, and drain, ground thoroughly, 46. Prepare for planting, lay open the holes for trees, 97. Rake leaves off borders and quarters, fweep, &c. 54. Gravel walks, and grass plats, cleanse, roll, mow, 54. Turf will be well laid now, but do the work foon. Caterpillars, deftroy, for they do mischief rapidly. Thin, by hoe, fpinach, &c. fmall crops, by hand, 49. Prick out cabbages for winter or spring planting, 211. Hoe between rows of cabbages, &c. and earth up, 49. Blanch celery and finochio by earthing; endive, beet, and chardons, by tying, 217, 256, 221, 208, 218. Cauliflowers that are heading, break leaves over, 216. Asparagus beds and feedlings, drefs, second week, 205. Strawberries, if not before, drefs out of hand, 165. Raspberries, dress, and plant coleworts between, 165. Seeds gather regularly and lay up thoroughly dry, 59. Fruits, gather carefully, and house well, 262, 274. Dig up, and store clean and dry, carrots, 214; potatoes, 237; parsneps, 230; ferusalem artichokes, 222.

Dress about current and gooseberry bushes, by digging in a little manure, cutting the ends of the roots. Herb-beds should always be dressed at this time, 246. Vines, wall-trees, &c. regulate, if not fully prune, 143. Grapes bagged in gauze, see to, lest they get mouldy. Shrub, &c. dig about, and put in good order, 111.

#### SOW

Beans, mazagan, third and fourth week, 207. Pear, ditto, early forts, 231. Lettuces, first week, warm border, 226. Small fallading, warm border, under glass, 249. Radishes, early purple short top, or early Sandwich, may succeed, south aspect, 240. Carrots, a few early horn, warm border, may be tried, 214.

S.5

## PLANT

galiyar lilk relle eigerfrey all her leithele

Anjou cabbage and boorcole yet plant. Brocoli, a few plants, first week, for latest spring use. Coleworts, first week, 219. Cabbages, any time, chusing strong plants, 211. Endive, first week, warm border, 220. Celery, first week, open ground, for late spring use, 217. Caulistowers, settle soon, 214. Lettuces, 226. Shalots, garlick, rocambole, (dry ground) 243, 221, 255. Strawberries, first week, 39. Wall-trees, and other shrubs, any time, but evergreens, first week, Herbs, rooted sorts, 246, &c. Mint on a little heat, protecting it, 253. Layers of trees and shrubs made last year; being rooted, take up well, and plant immediately, 97, &c.

### PROPAGATE

Trees and shrubs, by suckers, 64. By layers of the young wood, roses, jasmines, bay, laurel, laurustinus, vines, figs, filberts, codlins, mulberries, &c. See lists of trees and shrubs, 66. By cuttings or slips, gooseberries, currants, berberry, jasmines, honey-suckles, laurels, box, &c. 66. See lists, sect. 19.

#### FLOWERS.

Look over, trim, tie up, gather ripe seeds, &c. 55, 56, 59. Geraniums, and other tender plants, dress, house, 362. Auriculas and carnations in pots, preserve from much wet, and set in sunny situations, 358, 359:

Seeds, or feedlings, in pots, or boxes, ditto, and shelter from the cutting N. E. winds, 359.

Annuals, felf-fown, &c. may be taken up with a little earth, and planted where wanted, 281.

Biennials, plant out, but leave a few for spring, 282.

Perennials, ditto, also slip or divide old roots, 285.

Bulbous or tuberous, and fleshy roots of spring and summer flowers, plant, but the earliest first, 285.

Minionette, pots of, house, or put under glass. Saxifrage, pyramidal and double, plant in pots, 356. Edging of dwarf flowers, box, &c. plant, or repair.

#### NURSERY.

Stir, and fork in a little short well rotted manure, 70. Dig ground to be planted, a week before it is wanted. Sow feeds of trees, &c. and guard against mice, &c. 72, 79. Transplant seedlings designed for stocks, &c. 72. Suckers of plums, cuttings of quinces, collin, &c. 74. Prune, or dress up, young trees and shrubs from suckers, straggling shoots, and form the heads, 73. Dig about ditto for purposes as directed, 79.

## NOVEMBER.

THOUGH the last be the better month for planting, yet this is more commonly the time adopted: It cannot be now proper to delay it. The leaves not being all off should be no obstacle.

The object of pleasure should not yet be given up; and let the gardener do all in his power to be cleanly and neat, giving his grounds that proof of good culture, which is so essential to his credit.

Anticipate winter, so as to put all in order, and furnish the ground early; provide against frost, lest it come unawares.

# beauty bus MISCELLANEOUS WORK.

Wet, if it stands any where, let it be drained off.

Vacant ground, dig, manure, trench, or at least hoe, 46.

Clear away dead plants, leaves, weeds, and all litter, 54

Weed borders and crops, as spinach, winter onions, &c.

Grafs plats, cleanse, roll, mow, and lay turf, but soon.

S 6

Gravel

Gravel walks, weed, clean, and roll hard after rain, 54. Composts, collect, and mix well the materials for them. Cucumber and melon earth, flore in dry time, 178, 195. Earth up peas, beans, celery, cauliflowers, &c. 49. Blanch endive, 221, chardons, 218, and finochio, 250. Dig up carrots, potatoes, Jerusalem artichokes, and parsneps, but not all the latter, 230. Also when in prospect of frost, some red beet, scorzonera, salsify,

and horse-radish, all of them to be preserved a while in a cellar, or longer in dry fand. See cauliflowers farther on.

skirrets, Hamburgh parsley, leeks, turnep-radishes,

Lettuces in frames, under hand-glasses, &c. attend, 226. Artichokes, cut, see to, when in prospect of frost, 202. Asparagus, dress beds of, and also seedlings soon, 205. Raspberries, dress in the first week; see last month.

Hot-beds may be used for small fallading, 249, mint, 253, lettuces, 227, or for radiflies, 239.

Frost, consider what should be protected from it.

Fruit, latest forts, gather in the first week; and manage that already housed, 262.

Onions, store of, look over to remove decayed ones, 229. Seeds, dress, put up clean and dry, and keep them so. Caterpillars on winter greens, fearch for in time.

Grubs about the roots of lettuces and fearch for, 227. Shrubs, prune and dig about; fasten trained ones, 111.

Prune all trees, except figs, but cherries the first, 143. Figs, pull off green fruit, fasten shoots, 151.

Cover the roots, and fake new planted trees, &c. 102. Cauliflowers under glaffes attend to, and those in head, break leaves over. This vegetable, and brocoli, may be taken up when in prospect of frost, and planted

with balls of earth, or only laid in a cellar, where they will keep (perhaps) a month; but tie the leaves together at the tops with strong bass or a hay-band

before they are taken up, 216.

#### SOW

Small fallading and lap lettuce, under glass, warm border, or rather on a little heat, 227, 249. Radishes, purple short top, second week, warm border, 238. Carrots, early horn, 214. Beans and peas first week, for a principal early crop, 207, 231.

#### PLANT

Celery yet, 217. Lettuces, 226, and cauliflowers yet, in frames, under hand-glasses, or close under a south wall, 214. Endive ridged, 220. Coleworts, 219. Cabbages, 211; and all in the first week, though the latter may be later. Mint on heat, 253. Wall-trees, and others soon, 30, &c. 95, &c. Shrubs, deciduous, but not evergreens, 117, &c. Strawberries, upon necessity, but do it first week, 39.

### PROPAGATE

See last month, by suckers, slips, division, cuttings, and layers, as roses, &c. 64, &c.

#### FLOWERS.

Take up dead flowers, and tie up those in blow, 55, 56.

Frost, beware of, as to the care of tender flowers, 362,

Auriculas and carnations in pots, protect, 359, 361.

Seedlings in boxes, &c. place in the sun, and protect.

Pots of hardy flowers are themselves preserved, as well as the plants, by plunging above their rims, 358.

Bulbous and tuberous roots, plant and protect, 286.

Biennials and Perennials hardy, plant early, 283.

Thrist, plant or repair, as soon as may be, also box.

#### NURSERY.

See last month; and do foon what was then omitted.

Cover the roots of newly planted things and lightly all feed beds and feedlings of tender forts, 99, 69.

# DECEMBER.

THE garden is no longer a decorated scene; but it contains many things of promise, which demand attention, and which the industrious gardener will afford, agreeable to the culture that each requires.

There are still some works of labour; and where there is plenty of dung and frames, hot-beds may be

made use of, and spring anticipated.

If this month be called dreary, yet still the face of nature has charms, and invites us fometimes abroad, even when covered with snow. Frost is clearly beneficial, it dries the path, it strings our nerves, exhibitates our spirits, purifies the air, and prepares the ground for suture produce.

All nature feels the renovating force
Of winter, only to the thoughtless eye
In ruin feen. The frost-concocted glebe
Draws in abundant vegetable foul,
And gathers vigour for the coming year.

THOMSON-

#### MISCELLANEOUS WORK.

Weed crops, &c. clean up litter, and still be neat, 54.
Gravel walks, roll hard, if dry, against wet and frost.
Grass plats, cleanse from worm casts, sweep and roll.
Mice traps, set about peas, beans, cauliflowers, &c. 233.
Caterpullars in trees, snails in walls, and slugs, see after.
Tools, make, repair, grind, and keep bright, 276.
Seeds, look over the stock to keep them clean and dry.
Fruit and onions, examine, remove decaying, 229, 263.

Straw, damp or musty, remove from store rooms. Froft, guard against the ill effects of every where. Wheat straw, uleful to protect things, see radish, 238. Vegetables, before hard frost, take up, see last month. Artichokes, asparagus, and raspberries, (if not before) give their winter dreffing to foon, 202, 205, 164. Endive, tie up when perfectly dry, and ridge some, 220. Earth up (dry) celery high, also cauliflowers, chardons, brocoli, favoys, cabbages, &c. pressing the mould. Cauliflowers and lettuces in frames, &c. manage, 214, 226. Planting, prepare for, and open the holes ready, 29, 97. Vacant ground, clean, dung, rough, dig, or trench, 46. Barrow, make use of when frost to wheel in dung, &c. Hot-beds, see and manage the materials well for, 170. Cucumbers may be fown in the last week, 174, 176. Composts, make, and incorporate well by turning over. Orchards, prune trees, dress, dig, or plough the foil, 43. Prune wall pear trees, espaliers, and shrubs, 153, 160. Hedges, ditches, and drains, manage as the case requires. Drain wet from orchard, garden, nursery, &c.

#### SOW

Spring, have a conftant eye to, and prepare things for.

Beans, 207. Peas, 231. Radishes, 238. Carrots may be tried as radishes. Lettuces ditto, under glass in a warm border. Small sallad, as cress, mustard, and lap lettuce, on a slight heat, 227, 249.

### PLANT

Mint on heat, 253. Trees and shrubs of the hardy deciduous kind, in open weather, covering the roots and staking; if against a wall fasten them to it, 97, &c.

#### PROPAGATE

By Suckers, cuttings, layers, &c. see October, 64, &c.

FLOWERS.

HIMITS

#### FLOWERS.

Take care of, but neither fow nor plant; yet some chuse to sow auriculas in this month, 359.

Covering of every kind is to be no closer, or longer kept on than necessary, for great danger arises from much nursing, when plants come to be exposed again. See last month.

Auriculus see to, and take off dead leaves, 358.

Carnations guard against mice and much wet, 361.

Pots of hardy flowers, to protect, see last month.

#### NURSERY.

Protect, as the weather may require: all new planted things, cover the roots of them well, 99.

Seedlings of tender things may be covered lightly all over, but uncover in time, 69, 73.

Frost-cracks in seedling beds, fill up with sisted mould.

Wet (much of) gives frost so great hold, that it should be particularly guarded against.

Vermin must be attended to, particularly mice, which are apt to bark, and so kill young trees, 73.

### CLOSE.

Nature attend! join every living foul,
Beneath the spacious temple of the sky,
In adoration join; and, ardent raise
One general song.——
Soft roll your incense, berbs, and fruits, and flowers,
In mingled clouds to HIM, whose sun exalts,
Whose breath persumes you, and whose pencil paints.

SERVICE OF

# HINTS

ON THE

# METHOD OF MANAGING POND-FISH.

THE quantity of Fish to be supplied obviously depends upon the quantity of water, which should be divided, where it conveniently can, into five ponds; these may be distinguished by the five first

figures, as, 1, 2, 3, 4, 5.

Number 5 is intended for Breeding, and should be double or treble the fize of any of the other ponds. Or if this be inconvenient, there may be two marked No. 5. This pond may likewise be the most distant from the house. If the Breeding Pond should fail to answer this purpose, it will at least serve as a conservatory for Fish of small size, to be obtained elsewhere: and indeed fresh stores in any case will be sound desirable. The contents of this pond in Carp and Tench, or the greatest part, should be taken out annually in September, or October, counted in braces; and such as are from five to seven inches long thrown into No. 4.

The contents of No. 4, when grown one year from the length of five or feven inches, must be put into No. 3. The contents of No. 3, having grown one year from No. 4, must be removed into No. 2. And in like manner the contents of No. 2, after one year, must be removed into No. 1, which is to contain only such Fish as are sit for the table. It is obvious that this pond, for safety and convenience, should be the nearest to the house.

As No. 5 is to be the largest water, so No. 1 is to

be the least; the rest, of fizes between the two.

The shape of No. 1 should be oblong, for the convenience of the net, and the less disturbance of the Fish in taking out what are wanted from time to time.

A book should be kept by the Gardener, of the num-

ber and fize of each kind in every pond.

Carp are fit for the table from three to seven pounds each. Tench from one pound and a half to three pounds each. Perch from three quarters of a pound to one or two pounds, &c.

It is supposed that none of the ponds have a firong

current of very cold, acrid, innutritious water.

One acre of water upon a loam, clay, or marl, or any of these with a mixture of gravel, has been stated to be capable of supporting 2000 pounds weight of Fish: the number of the Fish making that weight being immaterial.

Carp and Tench breed most freely in ponds, or pits newly made. Tench likewise in almost any ponds,

where cattle are admitted.

It is evident that Perch and Pike should not be admitted in any degree in No. 5; but in all the other numbers, besides their own value, they are of important service, provided that they are strictly confined to a fize greatly subordinate to that of the Carp, or Tench. For they destroy not only the accidental spawn of Fish which breed, but also several Animals, whose food is the same with that of Carp and Tench, as Frogs, Newts, &c. Pike above the weight of one or two pounds must not be admitted even amongst Carp of the largest size and weight.

With

In

With regard to the absolute weight of Fish, which any particular pond will support, this can only be determined by observation and experience; as it depends on the different degrees of nutrition in different waters. It is said, that Carp and Tench in waters which seed well, will, before they are aged, double their weight in one year.

The third part of an acre in No. 1 would probably be fufficient for the demand of any family. For, upon the calculation above given, it would support near 700

pounds of Fish, which might be divided thus.

50 Brace of Carp, of three pounds each and upwards.

50 Brace of Tench, of two pounds each and upwards.

50 Brace of Perch, of one pound each and upwards.
That is, three Brace of Fish, weighing at least twelve

pounds for the use of every week.

Allowing one acre for No. 5, one third of an acre for No. 1, and one acre and two thirds for the intervening numbers, the whole water would be three acres. Upon this calculation the flock of No. 1 at 8d. per pound, would be worth 23l. 6s. 8d. per annum, and the expence annually of changing the Fish from No. 5 to 4, &c. will not exceed 1l. 6s. 8d. So that the value of each acre would be at lowest 7l. 6s. 8d.

annually.

e

0

g

No. t being supposed to be near the house, and at no great distance from the garden, if the Fish should not thrive sufficiently, which will be seen by the disproportioned size of the head, and the whiteness or paleness of the scales, they may easily be supplied with more food by loose peas from the garden, the sweeping of the granary, worms saved by the Gardener in digging, and the offal of the poultry killed for the kitchen; or by letting down the water about two seet, in the spring or summer, where there is a sufficient supply, and sowing the sides with oats, barley, rye, or wheat, very lightly raked in, and then stopping the sluice again.

In ponds already stocked, but not accurately regulated, it would be advisable to begin with that which has the most Pike, otherwise with No. 4, or what is intended for No. 4, and throw all the Fish under five inches length into No. 5, and the larger, according to their fizes, into the other numbers: and so on with

No. 3, 2, and 1.

Store-Fish procured elsewhere, if taken in summer, should be moved in the night in clean straw, wetted occasionally after they are packed: except Perch and Pike, which can only be carried in clean pond or river water. In moving Fish from one Pond to another, they should be first put into tubs of water already prepared for them, and afterwards carried in buckets without water. In taking Pike, or Perch, great care must be observed to avoid raising mud in the water.

In Breeding Ponds all water-fowls, as Geese, Ducks, &c. should be discouraged; and Herons carefully destroyed. If any white Fish, as Roach, Dace, &c. should be found, they are to be taken out; and if there be a spare piece of water for large Pike, they should be

put into it as food for the Pike.

Eels may be put with advantage into any except the Breeding Ponds, in lieu of Perch. The most easy way of taking them is by trimmers laid over night, baited with small Fish, not with worms: otherwise they may catch the Carp; or a small thief net may be baited with white Fish.

Common sewers and drains from the laundry are prejudicial to fish: so are the leaves falling from trees in great quantities. The use of grains should likewise be avoided in large quantities, as having little nutriment

whilft they are thus washed by the water.

It seems better for the use of the table, as well as more humane, to kill Fish designed for food by an incision with a sharp-pointed pen-knife, or punctures made with a pin longitudinally into the brain, about half an inch or an inch, according to the size of the Fish,

Fish, above the eyes. As this produces an instantaneous effect, it would probably save the cruel operation of crimping or flaying fish while alive; as in the case of Pike and Eels.

S

0

It is obvious, that this method of regulating Fish will apply with its full effect in larger spaces of water: it will likewise apply in a considerable degree to smaller pieces: even where the change is but from a pond for the use of cattle to a single canal in a garden.

In fituations near the great inland manufactures, and near the turnpike roads leading from an easy distance to the metropolis, water may be made by this kind of management, with little trouble or expence, to produce a large annual rent. See Preface.

A page or two to spare induces the Author to reprint the following Essay from the first Edition, and which was omitted in the second.

ON THE

# PROFESSION OF A GARDENER.

HE who undertakes the profession of a gardener, takes upon himself a work of some importance, and which requires no small degree of knowledge, ingenuity, and industry, to perform well. There are few businesses which may not be learned in much less time than that

of a gardener can positibly be.

It often happens, however, that a man who has been very little in a garden, and that only as a labourer, who can do little more than dig, or put out cabbage plants, will call himself a gardener; but he only is worthy of the name who having had much practice in the various parts of horticulture, possesses a genius and adroitness, fitting him for making experiments, and for getting through difficulties that the existing circumstances of untoward feasons, &c. may bring him into. He should possess a spirit of enquiry into the nature of plants and vegetation, and how far art (in his way) may be made fuccessfully useful, or at least probably so. The mode of growth, the pruning, the foil, the heat, and the moisture that suits particular plants, are not to be understood without a native taste, and close application of the mind. "Gardening depends more upon the labour of the brain than of the body." There

There are few things to be done in a garden, but which require a dexterity in operation, and a nicety in hitting the proper season for doing it. A gardener should be a fort of prophet in foreseeing what will happen under certain circumstances, and wisely cautious to provide (by the most probable means) against what

may happen.

A man cannot be a good gardener, except he be thoughtful, steady, and industrious; possessing a superior degree of moral excellence, as well as genius and knowledge adapted to his business. He should be modest in his manners and opinions. It too often happens with those who have much practical skill, that they slight what is written upon subjects of their profession; which is a fastidious temper, that the man of real merit will hardly possess.

The knowledge of botany is not necessary to the business of a practical gardener, but it might be made useful to him, or at least a matter of amusement and relaxation, enabling him to be respectably communicative. Some knowledge in this way ne will perhaps not content himself without, if he has any thing to do with the green-house, and hot-house, as many curious

plants are admitted there.

The character of a gardener is here fet high; but it is the goal of respectability at which he ought to aim, who presumes to call himself a professed one; and no doubt there are many in noblemen's and gentlemen's services, who are thus respectable in their abilities and

conduct.

It remains for the employer to consider the merits of his gardener, and reward him accordingly. He should reslect upon the importance of his garden to himself, samily, and friends; and how great difference there is between one well, and one ill managed. If the soil and situation is untoward, or the season cross, (which in England is very apt to try a gardener's skill and patience) he should be ready to make allowance, as there

there is little to be done in working against nature; and to the most attentive and skilful in the art of gardening, accidents will fometimes happen, that might have been prevented. "In the work of a garden there is no fuch thing as always proceeding with certainty,

and infuring fuccefs."

A gentleman should consider that he who furnishes him with fruits and vegetables, almost lives in the garden; and that he cannot relax in his duty without his neglect being manifest, by ferious consequences following it. There is always something for him to do, that must be done now, to sow, plant, prune, dress, &c. &c. Whoever will give himself the pains to trace a good gardener through the feveral stages of his employ, in all feasons of the year, will find it to be one continued circle of labour and toil."

A gardener is, in many respects, differently situated to the other fervants about a gentleman's house, and these discriminating circumstances, are what may be faid (according to general estimation) not to his A gardener has reason, indeed, to love advantage. his employment, as he meets with health and tranquillity in the exercise of it; but considering what he is, and what he does, in his proper capacity, he may justly claim a superior degree of estimation and reward.

FINIS.
